## EXECUTIVE SUMMARY

On November 21, 2021, a fuel spill occurred from AFFF containment drainage piping in the Red Hill Tunnel complex. At the time it was reported this leak occurred from the fire protection system. As a result of this a Statement of Work for Architecture/Engineering services was instigated to perform an assessment at the Red Hill Bulk Fuel Storage Facility at Joint Base Pearl Harbor Hickam. This work included a comprehensive assessment of the fire protection systems installed in the Red Hill Tunnel.

A site assessment of the fire protection systems at Red Hill Bulk Fuel Storage Facility (Red Hill) was undertaken by Jensen Hughes from 21 March – 1 April 2022. The purpose of the assessment was to perform a comprehensive review of each Fire Protection System, documenting the current condition and comparing the installed conditions with the design conditions, to investigate how the active fire protection systems including the retention line and retention tank performed during the events of May 6 and November 21, 2021 and to examine the Inspection, testing and maintenance that has been performed on the fire protection systems and compare it with the requirements of UFC 3-601-02.

The assessment of the fire protection systems revealed that the overall condition of the fire protection systems was very good with most of this equipment having been constructed as part of project FY 15 MILCON P-1551 Upgrade Fire Suppression and Ventilation Systems Red Hill Bulk Fuel Storage Facility, completed in 2018. Several recommendations were made to correct code deficiencies. The apparent unreliability of the Kingfisher Fire Alarm Radio Transmitter was the most critical of these recommendations.

A review of the events of May 6<sup>th</sup> and November 21, 2021, revealed that fuel was lifted by sump pumps into the AFFF containment piping because of a large spill on May 6<sup>th</sup>. This action was not intended by the sequence of operations of this system – changes made to the sequence during construction required this system to be interlocked with the fire alarm system – which was not reported to have been operated on May 6<sup>th</sup>. A manual should be developed that documents the complete sequence of operation of these systems and these systems should be recommissioned to confirm their sequence of operations.

After this assessment was begun the Navy announced that they intend to return the Red Hill Bulk Fuel Storage Facility to operation so that it can be decommissioned as a fuel storage facility. As a result of this recommendations for significant design changes for the AFFF containment drainage system and changes to the fire protection Inspection, Testing and Maintenance program do not appear to be warranted. Similarly, recommendations for betterments for the system are only necessary if the facility is to remain as a fuel storage facility.

## PART 1 – SITE ASSESSMENT AND ENGINEERING EVALUATION

A site assessment of the fire protection systems at Red Hill Bulk Fuel Storage Facility (Red Hill) was undertaken by Jensen Hughes from 21 March – 1 April 2022. The purpose of the assessment was to:

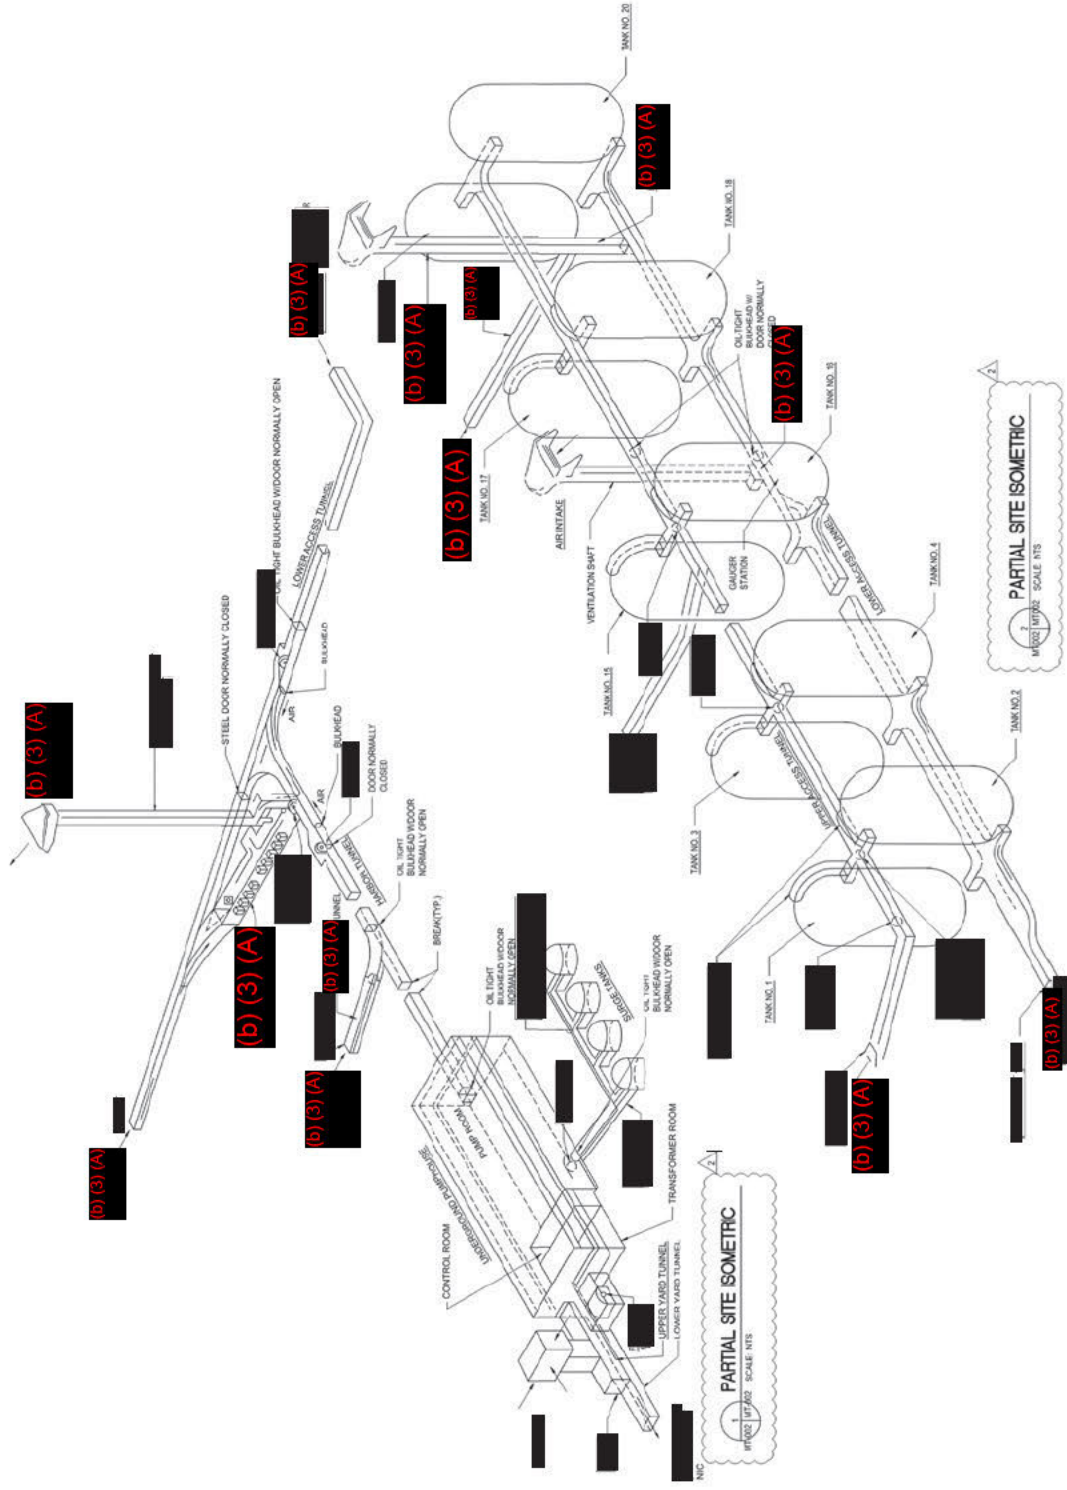

1. Perform a comprehensive review of each Fire Protection System, documenting the current condition of the fire protection systems including:
  - a. A general description and summary of each system reviewed.
  - b. Confirmation that the active fire protection systems were installed as designed in project FY 15 P-1551 – Upgrade Fire Suppression and Ventilation Systems, highlighting any variance of installation over designed conditions.
2. Summary of system performance May 6th and Nov 21.
3. Confirm the fire protection systems satisfy the recommendations of the 2010 Audit Report – Department of the Navy Red Hill and Upper Tank Farm Fuel Storage Facilities.
4. Identify pathways for fuel to get into the containment system.
5. Maintenance records review including a maintenance summary of each system versus requirements of UFC 3-601-02.

### 1. RED HILL SITE LAYOUT

The Red Hill Bulk Fuel Storage facility consists of a series of 20 – 300,000BBL (12.6M gal) underground fuel storage tanks. The 20 fuel tanks are located as 10 pairs of tanks with access tunnels located near the top and bottom of the tanks running between the pairs. The Upper Access Tunnel can be accessed directly via (b) (3) (A) entrances – (b) (3) (A). There are two elevators connecting the Upper and Lower Access Tunnel areas. (b) (3) (A) connects the Upper Access Tunnel to the Lower Access Tunnel, with a stop approximately midway between the Upper and Lower Access Tunnels, at the end of the (b) (3) (A) access tunnel. (b) (3) (A) connects just the Upper and Lower Access Tunnels. The Upper Access Tunnel is provided to access the top of the storage tanks and runs from Tanks 19 and 20 to (b) (3) (A). The Lower Access Tunnel is longer than the Upper Tunnel, it continues beyond Tanks 1 and 2 down the hillside eventually coming to a junction at the water pumping station, where the Harbor Access Tunnel splits off. The Lower Access Tunnel continues from the split to (b) (3) (A). While (b) (3) (A) serves as a discharge point from the Lower Access Tunnel, the Harbor Access Tunnel continues (b) (3) (A) to the Underground Pumphouse and (b) (3) (A) at Pearl Harbor. The Harbor Access Tunnel can also be accessed from (b) (3) (A) via the (b) (3) (A) Tunnel.

An isometric of the tank and tunnel layout can be found on the following page.

## 2. FIRE PROTECTION SYSTEMS SUMMARY

The fire protection systems installed at Red Hill include the following:

### A. Class I Standpipe System

A looped 8-inch sprinkler/standpipe main boosted by the fire pump serves all fire protection systems within the tunnel. These systems include standpipes for Upper and Lower Tunnel, preaction sprinkler for Lower Tunnel and various wet pipe sprinkler systems for Upper Tunnel, elevator shafts and gauger station areas. This 8" loop includes three main legs: 1) An exterior leg routed outside the tunnel from the fire pump house to (b) (3) (A) 2) An interior leg from (b) (3) (A) up (b) (3) (A) shaft, through the Upper Tunnel to (b) (3) (A) and, 3) An interior leg from (b) (3) (A) down (b) (3) (A) shaft through the Lower Tunnel to (b) (3) (A). The fire pump ties to this loop with an 8-inch line from the fire pump house near (b) (3) (A). Fire department inlet connections are provided outside the tunnel connecting to the 8" loop at (b) (3) (A). The standpipe system includes valves and outlets with automatic pressure regulating valves that are UL listed for fire department use. The standpipe outlets are placed at each tank junction and spaced at 200-foot increments designed for 500 gpm hose stream in the Upper Tunnel and 200-foot increments design for 1,000 gpm hose stream in the Lower Tunnel. These design flows comply with NFPA 14 requirements. The standpipe system is provided in the Upper Tunnel from tanks 1 through 20 (not including (b) (3) (A)), and in the Lower Tunnel from the new oil tight door up to the end of the Lower Tunnel at tanks 19 & 20. The standpipe system is supported by an electric fire pump to boost the pressure in the Upper Tunnel to comply with NFPA 14 to provide 100 psi at the outlet of the hydraulically most remote 2 1/2 in. (65 mm) hose connection.

### B. Preaction AFFF/Water Sprinkler System

Due to the hazards of (b) (3) (A) fuel lines with fittings, joints, valves, and other appurtenances that transfer fuel from the underground fuel tanks to/from the Pearl Harbor fuel pump house, the Lower Tunnel in the area of the tank farm was defined as an inside liquid storage area per NFPA. NFPA 30 requires inside liquid storage areas to be protected by a foam-water sprinkler system with 15-minute foam capacity. A preaction Aqueous Film Forming Foam (AFFF)/water sprinkler system, satisfying NFPA 16 guidelines, is provided for the Lower Tunnel area serving tanks 1-20. The system is designed for a density of 0.16 gpm per square foot over an area of approximately 10,000 square feet (one compartment) in accordance with NFPA 16. There are 5 preaction systems feed from the 8" sprinkler/standpipe main located in the Lower Tunnel. The preaction valves in each AFFF/water sprinkler riser are Viking flow control valves that regulate the water pressure downstream of the flow control valve.

Per NFPA 16 items such as storage tanks and proportioners for foam concentrates, pumps for water and foam concentrates, and control valves for water, foam concentrates, and foam solution, need to be located as near as possible to the hazard or hazards they protect but not be exposed to a hazard that

could impair the system. To satisfy this requirement, the five AFFF/water pre-action riser assemblies are provided within a 1-hour enclosure.

A triple IR flame detection system is provided to activate the preaction AFFF/water systems.

### C. Wet-Pipe Sprinkler System

As there are no fuel lines in the Upper Tunnel, this area is not considered as hazardous as the Lower Tunnel. Therefore wet-pipe sprinkler systems, meeting NFPA 13 guidelines, are installed to protect the Upper Tunnel. Two risers are provided Upper Tunnel #1 (UT#1) and Upper Tunnel #2 (UT#2). UT#2 also supplies water for (b) (3) (A) machine rooms and lobbies as required by UFC 3-600-01 for electric traction elevators. These sprinkler systems include all pipe, fittings, valves, sprinklers, and appurtenances necessary to support these systems. Adequate pressures are achieved without the aid of the fire pump. However, the fire pump was connected to the sprinkler systems to augment any pressure shortages due to larger than design fire areas being activated. The wet-pipe sprinkler systems are sized for a density of 0.4 gpm per square foot over an area of 2,500 square feet following Extra Hazard 2 (EH2) design requirements. An additional 500 gpm will also be available for use by exterior fire hydrants or standpipe system.

A wet pipe sprinkler system is also provided for the transformer room, gauger room, and electrical room in the Lower Tunnel. The riser for this system is in the Lower Tunnel fed from the 8" sprinkler/standpipe main.

### D. Water Supply System

All fire suppression systems provided require water supply to function. When designed UFC 3-600-01 stated that where onsite storage is a sole source water supply that the tank or tanks must be divided to ensure that more than 50% of the required storage is always available. To this end, a new 250,000-gallon water storage tank was constructed for the exclusive use by the fire protection systems of the Red Hill Bulk Fuel Storage Facility. The new tank was connected on the suction side of the fire pumps along with an existing 250,000-gallon water tank which ensures that the 50% of the storage capacity is available with one tank out of service. UFC 3-600-1 requires distribution mains to be looped to always provide 50% flow during a main break. A water line that runs along the upper access road supplies water to hydrants located at (b) (3) (A). This line also ties-in to the interior water line system the feeds all fire suppression systems and forms a fire protection main loop. The water tanks are supplied with water primarily from the booster pumps tied to the water supply at Pearl Harbor. There is an additional line from a Board of Water Supply (BWS) system which serves as a secondary source should the main source become unavailable.

### E. Fire Department Connections

NFPA 13 and NFPA 16 require two 2 1/2 in. NH internal threaded swivel fittings. NFPA 14 requires fire department connect to be sized per standpipe system demand with one 2 1/2 in. inlet for every 250 gpm of design flow. NFPA 14 requires 1,000 gpm flow rate calculation for standpipe system in a sprinklered building. Six 2-1/2" fire department inlet connections are installed at (b) (3) (A) NFPA 16 requires evaluation of fire department connection to avoid over pressurizing system components, imbalance of proportioning equipment, dilution of proportioned foam solution, and pressure and flows exceeding the foam system design. Each fire department connection should have signs indicating the following:

1. Per NFPA 16 to indicate "THIS CONNECTION FEEDS A FOAM-WATER SPRINKLER SYSTEM. DO NOT PUMP AT PRESSURES EXCEEDING [insert design pressure] UNTIL FOAM LIQUID SUPPLY IS EXHAUSTED. IF INCIDENT IS CONTROLLED BY FOAM BLANKET, DO NOT DESTROY FOAM BLANKET BY EXCESSIVE APPLICATION OF WATER, and
2. Per NFPA 13 and NFPA 14 to indicate "AUTOSPKR AND STANDPIPE".

### F. Fire Pump

The AFFF/water preaction and wet-pipe sprinkler systems are provided adequate water and pressure to operate correctly without the aid of a fire pump. However, per NFPA 14, a minimum operating pressure of 100 psi is required at the most remote standpipe hose connection. The system alone would not be capable of delivering the required 100 psi to the most remote standpipe hose connection throughout the Upper and Lower Tunnels, therefore an electric fire pump is provided to increase the pressure to 100 psi at all outlets. A second fire pump is provided as a backup but remains "OFF" until an operator manually turns the fire pump "ON". Though technically only required for the Upper Tunnel portion of the standpipe system, boosted pressure is also available for use by all suppression systems to augment pressures as deemed necessary by the fire department.

### G. Fire Alarm and Mass Notification System

The fire alarm and mass notification system was installed as part of the project to upgrade all fire suppression systems and the ventilation systems, Project FY15-P-1551. The fire alarm and mass notification (FAMN) system is a network of panels to allow command and control functions on a limited basis from multiple locations in the tunnel complex. The system uses Gamewell/FCI equipment (manufactured by Honeywell) to monitor and control fire alarm devices located throughout the Facility and interconnected/integrated with various auxiliary systems throughout the tunnel facility. Depending on the location within the Facility, the peripheral devices include manual fire alarm boxes, smoke and heat detection, duct-mounted smoke detection, and both addressable monitor and control modules to interface with various auxiliary system functions. Auxiliary systems monitored include:

- Fire sprinkler control valves and water flow switches
- Fire pump controllers

- Underground Pump House (UGPH) existing AFFF and FM-200 Releasing Panel (alarm, AFFF discharge, and trouble)
- Fire Suppression Water Tank Levels
- Aqueous Film Forming Foam (AFFF) fire suppression effluent retention tank levels
- Select Exhaust Fans for operation
- Compartmentalization and Oil-tight doors (local manual request for closure)

Auxiliary systems receiving an input from the FAMN system include:

- Release AFFF fire suppression systems in Lower Tunnel Tank Farm
- Activate AFFF pumps in the Fire Pump House
- Manual ON/OFF control of select exhaust fans associated with compartments in Lower Tunnel
- Activation (closure) of fire/smoke dampers
- Compartment roll-up and man door release
- Oil-tight door release and scissor-lift activation
- Elevator recall and shunt trip operation
- Elevator lobby door release

The FAMN system will also provide audible and visual notification throughout the tunnel facility utilizing speakers for both automatic and live voice message, and strobes.

The Lower Tunnel area is classified as a hazardous Class I Division 2 electrical environment, with the exception of the Gauger's Office, Gauger's Station Electrical Room, and the Office and Control Room areas of the UGPH. Devices located in the Lower Tunnel, outside of these specific rooms/areas are listed for installation and use in explosive environments.

The FAMN system is also connected to control and annunciation equipment using a dedicated fiber optic network. This equipment consists of graphic workstations with video display units (VDU), located in the UGPH Control Room, Gauger Office, each ADIT (tunnel entrance - total of six), and in Building 1757, a remote building outside the Tunnel Facility located at Pearl Harbor. The VDUs at the ADITs are enclosed in what appears to be temperature-regulated, weatherproof cabinets with a clear panel front. The network of graphic workstations provides the fire department with remote access and control of the FAMN system and ventilation systems from these same locations.

The FAMN system is monitored by the Base Fire Department using two Kingfisher Company, Inc. wireless communicators; one located at (b) (3) (A) covering the UGPH, (b) (3) (A) and the Harbor Tunnel systems, and one at (b) (3) (A) covering ADITs (b) (3) (A) Upper and Lower Tunnels, and the Fire Pump House. Connection of the FAMN system speakers to the base-wide mass notification system (Federal Signal Ultravoice) is provided by an Ultravoice Remote Interface (UVRI) cabinet located at the entrance to ADIT 1.

The equipment provided can vary by location in the tunnel complex, depending on the operating environment, auxiliary systems present, and the need for command-and-control functions, either on a limited or global basis. The following is a summary of the equipment by location.

UGPH/ADIT 1 – The Control Room in the UGPH is the location of the system “headend” equipment with all inputs annunciating here, and provisions for making live voice announcements, as well as controlling fans, smoke dampers, and releasing compartment doors associated with the tunnels. The fire alarm detection system installed prior to the project in 2015, which uses a Cheetah brand fire alarm control unit and also controls the existing FM-200 fire suppression system, was not replaced in 2015. It was retained, and remains operational, strictly for activation of the FM-200 system and to control the various fans in the UGPH during a fire emergency. It monitors a combination of heat detection and infra-red (IR) flame detection throughout the UGPH but has no associated notification appliances. The new fire alarm/mass notification system was installed with its own heat detection and IR flame detection in parallel with that of the existing system, along with manual fire alarm boxes (pull stations). It provides the live and automatic voice messages for the UGPH, along with visual notification using strobes throughout the building. Power for the equipment is derived from an emergency power electrical panel in the immediate vicinity of the panel equipment.

Harbor Tunnel – The main tunnel from the UGPH to the fuel tanks contains explosion-proof equipment consisting of pull stations, heat detectors, speakers, and strobes. There are also equipment cabinets in explosion-proof enclosures containing amplifiers, power supplies, etc. every few hundred feet to support the devices in the tunnel. Power for the equipment is derived from an emergency power electrical panel in the immediate vicinity of the panel equipment.

(b) (3) (A) Connection Tunnel – This is the entrance from COMPACFLT headquarters and connects with the Harbor Tunnel near the UGPH. It contains weatherproof equipment consisting of pull stations, heat detectors, speakers, and strobes. There are also equipment cabinets in weatherproof enclosures containing amplifiers, power supplies, etc. to support the devices in the tunnel. Power for the equipment is derived from an emergency power electrical panel in the immediate vicinity of the panel equipment.

(b) (3) (A) Connection Tunnel – This is an entrance at Red Hill and connects with the Harbor Tunnel nearest to the Tank Farm. It contains weatherproof equipment consisting of pull stations, heat detectors, speakers, and strobes. In addition, this is one of two locations where the FAMN system interfaces with the Digital Control System (DCS) panel DDC-9, which serves as an interface between the FAMN system and other systems in the tunnel (e.g., fire resistance-rated compartment door status, sump, and sump pump status, AFFF and groundwater retention system level, etc.) and their status. There are also equipment cabinets in weatherproof enclosures containing amplifiers, power supplies, etc. to support the devices in the tunnel. Power for the equipment is derived from an emergency power electrical panel in the immediate vicinity of the panel equipment.

(b) (3) (A) Connection Tunnel – This is an entrance at Red Hill to the Upper Tunnel of the Tank Farm at Tanks 1 and 2. It contains weatherproof equipment consisting of pull stations, heat detectors, speakers, and strobes. There are also equipment cabinets in weatherproof enclosures containing amplifiers,

power supplies, etc. to support the devices in the tunnel. Power for the equipment is derived from an emergency power electrical panel in the immediate vicinity of the panel equipment.

**(b) (3) (A)** Connection Tunnel – This is an entrance at Red Hill at the Upper Tunnel and connects to the Tank Farm between Tanks 15 and 16. It contains weatherproof equipment consisting of pull stations, heat detectors, speakers, and strobes. It also provides access to the Lower Tunnel and **(b) (3) (A)** Connection Tunnel using one of two elevators. In addition, there is a remote command panel equipped with: a network annunciator; a remote microphone; as well as fan, smoke damper, door, and speaker control switches. There are also equipment cabinets in weatherproof enclosures containing amplifiers, power supplies, etc. to support the devices in the tunnel. Power for the equipment is derived from an emergency power electrical panel in the immediate vicinity of the panel equipment.

**(b) (3) (A)** Connection Tunnel – This is an entrance at Red Hill which accesses the **(b) (3) (A)** Elevator at a level between the Upper Tunnel and Lower Tunnel. It contains weatherproof equipment consisting of pull stations, heat detectors, speakers, and strobes. It also provides access to the Upper and Lower Tunnels using the **(b) (3) (A)** Elevator. In addition, there is a remote command panel equipped with: a network annunciator; a remote microphone; as well as fan, smoke damper, door, and speaker control switches. There are also equipment cabinets in weatherproof enclosures containing amplifiers, power supplies, etc. to support the devices in the tunnel. Power for the equipment is derived from an emergency power electrical panel in the immediate vicinity of the panel equipment.

Lower Tunnel Tank Farm – This level is located at the bottom of the storage tanks and contains the pipes which transport the fuel to/from the UGPH. The Lower Tunnel contains explosion-proof equipment consisting of pull stations, heat detectors, duct-mounted smoke detectors for smoke damper control, IR flame detectors, speakers, and strobes. The IR flame detectors are used as part of the AFFF fire suppression deluge system present in this part of the tunnel complex. The FAMN system also monitors the door position of the compartment doors (man doors and roll-down doors). There are also equipment cabinets in explosion-proof enclosures containing amplifiers, power supplies, etc. every few hundred feet to support the devices in the tunnel. Power for the equipment is derived from an emergency power electrical panel in the immediate vicinity of the panel equipment.

Gauger Office – This office area is in the Lower Tunnel between Tanks 15 and 17, next to the passenger elevator from the Upper Tunnel. It is separated from the Lower Tunnel hazardous environment by fire and smoke resistance-rated construction which allows the use of non-explosion-proof equipment inside its area. This area has a remote command panel equipped with a network annunciator; a remote microphone; as well as fan, smoke damper, door, and speaker control switches. It also has one of the fire alarm control panels which monitors the IR flame detectors in the Lower Tunnel of the Tank Farm and houses the panel which activates the AFFF fire suppression systems in this same area. In addition, this is the second location where the FAMN system interfaces with the Digital Control System (DCS) panel DDC-1.

Upper Tunnel Tank Farm - This level is located near the top of the storage tanks, with ships ladders at the tanks providing access to the very top of the tanks. It contains weatherproof equipment consisting of pull stations, heat detectors, duct-mounted smoke detectors for smoke damper control, speakers, and strobes. While the shafts surrounding the ships ladders to the top of the tanks contain explosion-proof heat detectors, speakers, and strobes. The Upper Tunnel itself also has equipment cabinets in weatherproof enclosures containing amplifiers, power supplies, etc. every few hundred feet to support the devices in the tunnel. Power for the equipment is derived from an emergency power electrical panel in the immediate vicinity of the panel equipment.

Fire Pump Building – This building is located just below (b) (3) (A). It has a remote command panel equipped with a network annunciator; a remote microphone; as well as fan, smoke damper, door, and speaker control switches. The building houses: two fire pumps; the AFFF storage tank, two AFFF pumps, and an emergency generator. It is protected by standard pull stations, speakers, and strobes. The FAMN system also monitors the building wet fire sprinkler system, as well as the fire and AFFF pumps.

#### **a. Digital Control System**

The Digital Control System (DCS) consists of networked digital controller panels used to monitor and, in some cases control, systems associated with compartmentalization and remediation during a fuel fire or fuel leak in the Lower Tunnel Tank Farm. The DCS is not part of the fire alarm system, but the two systems communicate with each other. This network is used to monitor various systems associated with the removal and containment of the effluent from the activation of the AFFF fire suppression systems during a fuel leak or fire. The DCS monitors:

- Level of effluent in sump pits (float switch and high level).
- Associated sump pumps (four at each compartment door) for running, overheating, and water infiltration.
- High-level condition in retention tank.
- High-level condition in secondary containment area.
- Oil-tight door “close” request pushbutton and door position (open/close), scissor lift motion and position.
- Fire water tank water level (high/low).
- Groundwater level at compartment doors.
- Groundwater collection pumps running.
- Emergency generator fuel tank level and leak detectors (Fire Pump Building).

In turn, the DCS controls, provides local control of, or provides an output contact for:

- Sump pumps at compartment and oil-tight doors (hand/off/auto).
- Activation of audible and visual alarms indicating scissor lift and door activation at oil-tight door.
- Oil-tight door position and activation of local pushbutton associated with closing door manually.
- FAMN system monitoring of status for sump pumps and groundwater collection pumps running, sump high level, retention tank and secondary containment levels, pushbutton request to close oil-tight door, and fire water tank levels.

**b. Smoke Ventilation**

The Tunnel Complex has many supply and exhaust fans present throughout to maintain a tenable and safe environment. Command and control of the fans and dampers appears to be possible from a graphic control panel outside the entrance to (b) (3) (A) according to notes on the panel, not all fans in the complex are yet connected to it. The FAMN system has a limited role in the ventilation of smoke during or after a fire in the tunnels. It controls (b) (3) (A) fans (b) (3) (A) (b) (3) (A) ) in the Upper and Lower Tunnels in the Tank Farm area. It also controls the fire/smoke dampers in this area as well. The existing Cheetah fire alarm and releasing panel in the UGPH Control Room controls the fans located in the UGPH. The graphic fan control panels provided as part of the P-1551 project appear to indicate there are a total of (b) (3) (A) fans.

**H. AFFF Retention System**

The foam/water discharged from the AFFF/water preaction systems is collected by transverse trenches at each fire/smoke compartment in the Lower Tunnel. These fire/smoke separations segregate every four tanks into a separate compartment. The foam/water and any fuel from a fuel leak/discharge that sheet flows into these trenches is collected and routed to a sump pit, one for each 4-tank compartment area, these sumps are located near the downhill fire/smoke compartment separation. There are 4 large sump pumps in each sump pit (3 primary and 1 backup pumps) and these lift the effluent into a 14-inch AFFF retention line. This retention line is connected to a 153,000-gallon AFFF retention tank located outside of Adit 3. The tank is sized to accommodate a 20-minute discharge of the Lower Tunnel fire extinguishing system, plus an additional (b) (3) (A) fuel that could leak from the fuel system in the Lower Tunnel. The sump pumps are activated automatically on level controls and annunciate a supervisory alarm when operated. During construction changes were made to the sequence of operations of this system to require the fire alarm system to be in alarm before the sump pumps operate.

A separate smaller ground water collection pump is also located in the sump pits to collect and pump any incidental ground water seepage in the tunnel into the main slop tank sump pump pit located below tanks 1 and 2. This system is provided to prevent unintended operation of the main AFFF retention pumps. The ground water collection pumps are interlocked to shut down when the fire alarm system is activated.

The main AFFF retention sump pumps, and the ground water sump pumps are also interlocked to shut down if the new oil tight door is closed. This is done via the DCS, which monitors the closed position of the oil tight door via a door switch and is also interfaced with the sump pumps to shut them down. The new oil tight door is closed upon activation of the high groundwater float switch at the oil tight door, or activation of a manual push button at the oil tight door. During construction the sequence of operations was changed to remove closing on the oil tight doors upon receiving a signal from the fire alarm system.

The main AFFF retention tank is designed as an API 650 steel fuel storage tank as it may collect fuel from a fuel leak. The AFFF retention tank is provided with a containment berm to comply with environmental regulations for spill control.

#### **I. Ventilation and Smoke Control**

This facility currently has an operating ventilation system including several ventilation fans that are utilized to control the concentration of fugitive emissions of fuel fumes to below 25% of the lower explosive limit. It is desirable that these fans be able to exhaust smoke during or after a fire to be controlled by the fire department as they deem necessary. Currently, the fans are sized to control the smoke in most locations allowing occupants to egress prior to being overcome by smoke. The existing fans are tolerant of the heat of the smoke generated more than 3 feet from the fans. Fire closer than this will consume the fans and render them inoperable. The fans, however, are not explosion proof. The FY15 P-1551 project replaced mechanical/electrical motors of the fans to make them explosion proof in the Lower Tunnel, like the fire alarm system outlined above. Additional upgrades to the existing ventilation system for enhanced smoke control were not provided as part of the project. Similarly, the provision of self-contained breathing apparatus (SCBA) was not provided as part of the project.

### 3. FIRE PROTECTION SURVEY RESULTS

#### A. Condition of Fire Protection Systems and Comparison of Design Versus Installed Conditions

Over the 12-day period from March 21 to April 1, 2022, each of the fire protection systems was surveyed by a team of Jensen Hughes fire protection engineers. Surveys were conducted to compare the systems as installed to the as-built shop drawings provided from the FY 15 P-1551 project. Drawings of the survey results are contained in Appendices A through H.

##### a. Standpipe System

Site survey notes for the standpipe system can be found in Appendix A. Generally, the drawings provided as as-built drawings from the FY15 P-1551 did not appear to have been updated to reflect as-built conditions. This included how supply sprinkler piping was being routed and a few instances where the standpipe hose valve connections were installed in a different location.

The standpipe system itself was observed to be in very good overall condition. The hose valves are provided with pressure-regulating devices but were not provided with a valved outlet for a pressure gauge to be connected. A valved outlet should be provided for each location with a pressure-regulating device so a pressure gauge can be attached to verify the required pressure is being provided.

##### b. Preaction AFFF/Water Sprinkler System

Site survey notes for the preaction AFFF/water system can be found in Appendix B. Generally, the drawings provided as as-built drawings from the FY15 P-1551 did not appear to have been updated to reflect as-built conditions. There were many locations where additional sprinklers and/or additional branch lines had been provided and these are noted in the site survey notes. The location of seismic braces in many instances also did not match locations shown on the drawings. The backgrounds on which the drawings were prepared also seemed to have frequent inconsistencies with the observed field conditions.

The preaction AFFF/water sprinkler system itself was observed to be in very good overall condition. Significant external pipe degradation was observed in the riser for Preaction System 3 due to the constant dripping of ground water seepage into the riser closet and onto the piping. A ceiling should be constructed in this room, like the metal ceiling constructed in other areas of the Lower Tunnel, to stop water dripping in this room. Once water no longer dripping into this riser room the degraded riser piping should be replaced.

Site survey notes for the AFFF storage and pumping system can be found in Appendix D. The AFFF storage and pumping system, located in the fire pumphouse building, were also visually inspected, and appeared to be in very good overall condition. The foam pumps themselves were tagged out of service, this appeared to be due to a leak in the underground piping between the fire pumphouse and (b) (3) (A) where the foam concentrate piping enters the tunnel system. The system installation matched what was indicated on the as-built drawings provided.

The nitrogen generating system for the preaction system was observed to be in very good overall condition. The system as installed matched the as-built drawings provided.

#### **c. Wet Pipe Sprinkler System**

Site survey notes for the wet-pipe sprinkler system can be found in Appendix A. Generally, the drawings provided as as-built drawings from the FY15 P-1551 did not appear to have been updated to reflect as-built conditions. This included the routing of sprinkler piping, location of bulkheads/doors, and the number of branch lines installed in the access tunnels to the storage tanks.

The wet-pipe sprinkler system itself was observed to be in very good overall condition. Significant external pipe degradation was observed at various locations in the Upper and Lower Tunnels. There is sprinkler piping missing hangers on branch line; temporary ventilation ductwork obstructing sprinklers, sprinkler risers, and being supported by the sprinkler piping resulting in external loading not accounted for when designing hangers to support the sprinkler piping.

The “as-built” drawings should be redlined and incorporated into a new drawing to account for all field changes made during installation. Additionally, hangers need to be installed on unsupported piping and the temporary ventilation ductwork needs to be relocated.

#### **d. Site Water Supply**

The site water supply system installation matched what was indicated on the as-built drawings provided and was observed to be in very good overall condition.

#### **e. Fire Department Connections**

Site survey notes for the fire department connections can be found in Appendix A. The system installation matched what was indicated on the as-built drawings provided and was observed to be in very good overall condition.

The fire department connections were not provided with signs indicating the system they served, and the operating pressures required. The signs should be provided at each fire department connection are as follows:

1. Per NFPA 16 to indicate “THIS CONNECTION FEEDS A FOAM-WATER SPRINKLER SYSTEM. DO NOT PUMP AT PRESSURES EXCEEDING [insert design pressure] UNTIL FOAM LIQUID SUPPLY IS EXHAUSTED. IF INCIDENT IS CONTROLLED BY FOAM BLANKET, DO NOT DESTROY FOAM BLANKET BY EXCESSIVE APPLICATION OF WATER”, and
2. Per NFPA 13 and NFPA 14 to indicate “AUTOSPKR AND STANDPIPE”.

#### **f. Fire Pump System**

Site survey notes for the fire pump system can be found in Appendix C. The system installation matched what was indicated on the as-built drawings provided and was observed to be in very good overall condition.

**g. Fire Alarm and Mass Notification System**

Site survey notes for the fire alarm and mass notification system can be found in Appendix E. The upgrade of the fire alarm system was included as part of project FY15 P-1551 in direct response to findings and recommendations found in an audit conducted by Naval Audit Services and titled Department of the Navy Red Hill and Upper Tank Farm Fuel Storage Facilities (N2010-0049, dated 16 August 2010). Specifically, the audit referenced recommendations from a 1998 assessment which identified a need for emergency voice/alarm communication system in the RH facility to alert occupants of a fire or other emergency (Finding 3 Safety Measures). Based on our observations as to the extent to which the new system offers one-way voice communication to all areas of the Red Hill Bulk Fuel Storage Facility, it would appear the 1998 recommendation and 2010 audit comment has been addressed by the installation of this system. The overall physical condition of the system panels and devices appeared to be “good”, with no signs of damage. However, there were code deficient conditions associated with device placement, spacing/coverage, or obstruction.

In general, the as-built shop drawings provided (Revision 6, dated 23 January 2018) do not accurately reflect the installed device locations. For initiating devices (e.g., pull stations, heat detection, addressable monitor modules, etc.), approximately 5% - 10% of device locations were inaccurate. Most of the spacing of these installed devices appeared to maintain code compliance. However, it is estimated over 85% of the notification appliances were inaccurately located on the as-built drawings. Most of these devices still maintained compliance with required spacing, but a significant number of visual notification devices were over-spaced creating code deficient conditions. These devices are spaced beyond the maximum distance allowed by NFPA 72 of 100 feet. This occurs at several intervals, where a device will be spaced 110 – 120 feet from the previous device, and then 70 – 80 feet to the next device. There did not appear to be any field conditions which would contribute to the extended spacing. Spacing of these devices should be corrected so they are within the code required spacing. All devices in the entire length of tunnel from the Underground Pump house to the Harbor Tunnel intersection of Adit 2 were not accurately located on the as-built drawings. There are also numerous label errors, mostly of single, isolated devices, that should be corrected.

In addition, all of the explosion-proof strobes located in the Tank Farm portion of the Lower Tunnel are obstructed and violate NFPA 72. The code requires strobes to be visible by direct concentrated viewing (i.e., you have to be able to see the actual strobe lens from all parts of the corridor) in order to use corridor spacing of minimum 15cd strobes mounted up to 100 feet apart. The strobes in this section of the tunnel are mounted with the bottom of the strobe lens well above the adjacent pipe stand structure and pipes. Personnel on the actual walking portion of the tunnel will not be able to see the strobes at all.

There were also inaccuracies associated with equipment shown on the as built drawings not being installed, or installed in a different orientation (i.e., mounting on wall instead of ceiling, or vice-versa). Many of these examples involved duct-mounted smoke detection at smoke dampers, usually where installation of this type of device was not possible. However, there was no documentation indicating

the required detection was exempted nor was spot detection provided at the damper. Some of this may be attributable to the fact the drawings provided and reviewed would not necessarily reflect changes associated with Revisions R and S (dated 21 June 2018) of the design drawings, some of which affected systems monitored by the fire alarm and mass notification system.

#### **h. AFFF Retention System**

Ideally a foam retention system should operate by gravity flow such that discharged AFFF effluent and fuel may be collected via gravity thereby eliminating any moving parts. Unfortunately, it was determined during design that it was not possible for this system to operate under gravity. It would be ideal if drainage from the Adit 3 end of the tunnel into the retention tank could occur under gravity, however doing this would require finding a site for the tank where the top of the tank was below 98' elevation. Without significant additional excavation this would also require piping from the tunnel, which during a retention event would contain AFFF, to be located underground. There are numerous areas in the system where low points are provided and effluent collects at these points. The first low points are the 5 sump pits provided at each fire/smoke wall. Effluent drains to these pits and is lifted by sump pumps into the AFFF retention piping. The second collection of low points are those low points created when the retention line changes elevation in the tunnel to pass over doorways and other obstructions. Each of these changes in elevation creates a local localized low point which is eventually overcome by the overall grade of the tunnel and slope of the retention pipe. Low point drains were observed at these locations which permit the pipe to be drained at each of these individual low points. The third and final low point is created by the elevation of the retention tank, the drain line into the retention tank, and each of the 5 sumps. The bottom of the retention tank itself is noted as being at an elevation of 119', while the low point in the tunnels themselves at Adit 3 is 98'. During construction it was noted (RFI-0069) that all the tunnel retention piping to the point below the fire door between tanks 3-4 and tanks 5-6 is at or below the 119' elevation making the entire volume of the retention piping below this door a low point (~between 30,000 and 40,000 gals). As constructed the entry point in to the retention tank is at the top of the tank itself making the top of the tank the height that must be overcome for effluent to flow under gravity into the retention tank – the effect of this is to make even more of the retention line a low point, such that it is likely more than 40,000 gal of effluent would have to enter the retention line before any of it would flow into the tank. Any discharge from the tanks would have to fill the entire length of the retention line to Adit 3 to an elevation equal with the elevation of the top of tank entry before effluent could flow into the retention tank. For spills less than 40,000 gals no effluent will reach the retention tank, rather these spills will be held in the numerous low points throughout the system. An overall survey of elevations along the retention line, which was performed during the site survey, could be further developed, and used to evaluate where effluent is likely retained based on the location of effluent entering the retention system. A small sump and manually activated sump pump were provided at the low point of Adit 3 to be able to pump from the low point to a valved header at Adit 3 to allow fluid in the low point to be pumped to a tanker truck for disposal.

The AFFF retention system as finally installed did not match the as-built drawings. The retention system was constructed of HDPE pipe for the entire system. After installation changes were made to the retention system which are not reflected on the as-built drawings. These changes included:

1. Steel pipe and valves were installed for the system from the sump to the main 14-inch retention line.
2. The main 14-inch retention line was changed to steel pipe for approximately 100 ft from a point after the penetration of the fire/smoke wall to a point upstream of the sump piping inlet.
3. Spring operated control valves with a fusible link are in the piping upstream of the sump pumps and upstream of the pipe type junction.

These changes were not documented as part of the as-built drawings, and it is not clear that any acceptance testing of this altered system along with the already accepted fire alarm systems was undertaken.

There are numerous improvements that could be recommended to improve the operation of the retention system. However, at this stage with the established goal of ultimately taking the fuel storage tanks out of service within the next 2-3 years any recommendations for significant alterations to the retention system do not appear to be warranted.

#### **B. Fire Protection Systems Recommendations of 2010 Audit Report**

The 2010 Department of the Navy Red Hill and Upper Tank Farm Fuel Storage Facilities Audit report contained a list of 13 identified safety hazards. At the time of the report 7 of these hazards were identified as having been corrected, 2 were identified as outstanding but with funding having been secured for mitigation, and preventative maintenance was identified as ongoing. This left three remaining hazards that were identified in the Audit report. The report recommendations identified these items, as indicated below, and recommended they be prioritized as critical:

1. Install an automatic fixed fire suppression system at the lower tank storage area. NAVFAC Pacific engineers have recommended the installation of an Aqueous Film Forming Foam (AFFF) Deluge system.
2. Install an emergency voice/alarm communication system at Red Hill.
3. Upgrade the existing fire protection water main in the upper and lower tunnels at Red Hill.

Each of these Audit report recommendations was addressed by construction project FY15 MILCON P-1551 Fire Protection, which included the installation of:

1. Five (5) foam water preaction systems in the Lower Tunnel. As part of this system a new fire pump system was also provided that boosts the water supply pressure from the water storage tanks to the Red Hill Fire Protection Systems.

2. An emergency voice fire alarm and mass notification system from Adit 1 throughout the entire Red Hill Bulk Fuel Storage Facility.
3. An 8" looped fire protection main and standpipe & hose system throughout the Upper and Lower Tunnel areas.
4. A second water supply tank adjacent to the existing water supply tank to supply the Red Hill Fire Protection Systems.

The addition of these systems satisfies the outstanding fire protection/life safety recommendations of the 2010 Audit Report.

## 4. SUMMARY OF FIRE PROTECTION AND RETENTION SYSTEM PERFORMANCE

### A. May 6, 2021, Fuel Release Incident

A significant discharge of fuel occurred from a rupture of a fuel line in the Lower Access Tunnel at Tanks 18 and 20 at approximately 1812 hours on May 6, 2021. The root cause of the incident was the incorrect sequence of opening of fuel valves while fuel was being taken from Tank 12, with collateral damage and leaks occurring in the area around Tanks 18 and 20. This leaked fuel, once in the Lower Access Tunnel, flowed in the direction of the sump pits associated with Door C-1 at Gaugers office (south of Tanks 17/18), and potentially Door 5 (south of Tanks 13/14), respectively.

Ultimately most of this fuel discharge was collected by the retention system, however due to the significant number of low points and the relative elevation of the line into the retention tank at (b) (3) (A) compared with the tanks themselves, none of this fuel drained to the retention tank. As evidenced by the later discovery of fuel in the retention line however, it is unequivocal that fuel was lifted by the sump pumps into the retention line but there was no record of operation of the sump pumps on the day of the incident. Anecdotal reports from the day indicate that the fire alarm system in the tunnel was not in alarm during this incident. Sequence of operation changes made during construction of project P-1551 were supposed to interface the sump pumps with the fire alarm system such that they would not operate without a fire alarm. As evidenced by fuel being found in the containment system piping, it appears the installed sequence of operations does not match what is presented in the as-built drawings.

The fire alarm/mass notification (FA/MN) system does not, and is not required to, detect a fuel leak. It only detects conditions that could occur because of a fuel leak - ignition (flame detection) and fire (heat detection). Even with the manual pull stations provided, the normal procedure would not necessarily include activation during a fuel leak without ignition, or threat of ignition.

The indirect mechanisms in place to automatically notify and annunciate on the FA/MN system included the following auxiliary system interfaces:

- Fuel sump pump running at Door C-1; if sufficient fuel were to accumulate and cause the fuel levels to activate the individual float switches provided to engage the associated pumps.
- Fuel Sump pump running at Door 5; if sufficient fuel was able to travel this distance and cause the fuel levels to activate the individual float switches provided to engage the associated pumps.

The fuel sump pump float switches and pump running status are monitored by the Digital Control System (DCS). The DCS is the indirect mechanism that provides status inputs to the FA/MN for the following conditions:

- Sump "X" High Level Float Switch (1 for each sump), note that the high sump level float switch is located higher than all sump pump float switches in each sump pit.
- Sump Pump SP-Door-"X"-C1, 1 to 5 Pump Running (1 for each of the 5 pumps in each of the sumps)

Given the amount of fuel believed to be released, and reported observations made by personnel present during the leak, the sump pumps at Door C-1, at a minimum, accumulated enough fuel to activate the float switch and start the fuel sump pumps running in that door's associated sump pit.

The interface of the FA/MN system and the DCS occurs in two locations: at DCS cabinet DDC-9, near the (b) (3) (A) entry point; and at DDC-1 in the Lower Tunnel Gaugers Office. The FA/MN system uses addressable monitor modules to monitor the DCS outputs. At a minimum, the reporting addresses associated with Door C-1 would be (b) (3) (A). If any of the pumps activate, its corresponding address should appear as an input in the FA/MN history log.

Based on our analysis of the provided system history log, there were no inputs from these nodes (panels), much less these specific addresses, on the day of the leak event. It is not known as to why the fuel sump pump running status did not annunciate on the FA/MN system. The history log did not indicate any impairment of these associated panels on the day of the event. However, the fire protection ITM program indicates multiple occasions of a period of years where the Kingfisher failed to transmit signals to the Regional Dispatch Center.

#### **B. November 21, 2021, Fuel Release Incident**

A further fuel discharge occurred on November 21, 2021. This discharge was as a direct result of the May 6 incident. On this day a low point drain on the 14-inch retention line was hit by a vehicle (or something being carried on a vehicle) and broken. Fuel from the May 6 incident that remained in the retention line was then released to the Lower Tunnel. This occurred in the Lower Tunnel below the oil tight door. The only drainage in this area of the tunnel is directly to the groundwater aquifer.

The fuel from the retention line on November 21st appears to have been fuel that remained in the retention line from the May 6th incident. Due to system design all low points need to be checked, not finding fuel in the retention tank, or at the lowest point in the system is no guarantee that fuel is not in the system because it will be retained at the first low point below where fuel enters the system, until this low point is overcome and then it will accumulate at the next low point down the line. Due to the low slope and large diameter of the retention line this can mean significant pockets of fuel are retained at low points in the middle of the system.

## 5. MAINTENANCE RECORDS REVIEW

UFC 3-601-02 7 October 2021 contains maintenance requirements for fire protection systems. It should be noted that this UFC was updated after the project and the current fire protection maintenance contract. Items that are new to this edition of the UFC are shown shaded in these tables. The requirements for each system type are contained in sections A through I, there are no fire protection testing requirements for the AFFF retention system.

### A. Standpipe System

Hose outlets and FDCs inspection, test and maintenance is conducted with the wet pipe sprinkler system. See Section C – Wet Pipe Sprinklers for more information.

## B. Preaction AFFF/Water Sprinkler System

## Lower Tunnel Preaction Maintenance Summary (Systems 1-5)

Frequency	Component	Sub-component (if applicable)	Task	Record of Completion	Date
Semi-Annually	Foam concentrate		Inspect for quality and evidence of sludge or deterioration Verify adequate supply		
Annually	Control valves (sealed, locked, or electrically supervised)		Verify proper valve position	Yes	06/20/2021 (RHT Lower Tunnel DS1 - June 20, 2021) 06/20/2021 (RHT Lower Tunnel DS2 - June 20, 2021), 06/20/2021 (FLC AFFF ZONE 5 PA_DS 6.20.21) 06/20/2021 (FLC AFFF ZONE 4 PA_DS 6.20.21), 06/20/2021 (FLC AFFF ZONE 3 PA_DS 6.20.21)
	Waterflow alarm devices		Operate alarm test valve to verify initiation and receipt of alarm Verify alarm test valve alignment and tamper switch (if sealed or electrically supervised)		
	Pre-action valve and trim		Inspect the exterior of valves, gauges, trim alignment	Yes	06/20/2021 (RHT Lower Tunnel DS1 - June 20, 2021) 06/20/2021 (RHT Lower Tunnel DS2 - June 20, 2021), 06/20/2021 (FLC AFFF ZONE 5 PA_DS 6.20.21), 06/20/2021 (FLC AFFF ZONE 4 PA_DS 6.20.21), 06/20/2021 (FLC AFFF ZONE 3 PA_DS 6.20.21)
			Verify valve pressure and legibility of the hydraulic nameplate Conduct a main drain test to verify supply (valve position)		
	Main drain			Yes	6/20/2021 (static only) (RHT Lower Tunnel DS1 - June 20, 2021)

Frequency	Component	Sub-component (if applicable)	Task	Record of Completion	Date
			Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge	Yes	06/20/2021 (static only) (RHT Lower Tunnel DS2 - June 20, 2021), 06/20/2021 (static only) (FLC AFFF ZONE 5 PA_DS 6.20.21), 06/20/2021 (static only) (FLC AFFF ZONE 4 PA_DS 6.20.21), 06/20/2021 (static only) (FLC AFFF ZONE 3 PA_DS 6.20.21)
			Compare results with results from previous main drain tests and original acceptance test		
			Verify that the results are within acceptable limits or identify corrective measures		
	Fire department connection		Verify accessibility and condition		06/20/2021 (RHT Lower Tunnel DS1 - June 20, 2021) 06/20/2021 (RHT Lower Tunnel DS2 - June 20, 2021), 06/20/2021 (FLC AFFF ZONE 5 PA_DS 6.20.21), 06/20/2021 (FLC AFFF ZONE 4 PA_DS 6.20.21), 06/20/2021 (FLC AFFF ZONE 3 PA_DS 6.20.21)
			If caps are removed or missing, check for obstructions		
			Verify system check valve is not leaking		
			Verify gaskets are present		
			Lubricate if swivels do not rotate smoothly		
			Verify proper operation of ball drip drain prior to the cold season		
2 Years	Control Valves		Operate valve through entire travel to verify function	Yes	06/20/2021 (RHT Lower Tunnel DS1 - June 20, 2021) 06/20/2021

Frequency	Component	Sub-component (if applicable)	Task	Record of Completion	Date
			Lubricate valves and stems to ensure operability	Yes	(RHT Lower Tunnel DS2 - June 20, 2021), 06/20/2021 (FLC AFFF ZONE 5 PA_DS 6.20.21),
			Verify that valve supervisory switches detect a change in valve position	Yes	06/20/2021 (FLC AFFF ZONE 4 PA_DS 6.20.21), 06/20/2021 (FLC AFFF ZONE 3 PA_DS 6.20.21)
	Pre-action valve		Trip to verify proper operation		
			Verify function of manual actuators (if provided)		
			Inspect internal condition and clean valve seat before resetting		
	Low point drains		Drain all low points after pre-action valve trip test		
	Air supply (if present)		Test the automatic air pressure maintenance device		
			Test the high/low air supply alarms		
5 Years	Strainers		Clean and inspect the interior to verify condition		The system is not old enough to have required this testing.
10 Years	Gauges		Calibrate or replace gauges		
10 Years and every 10 years thereafter	Dry Sprinklers		Replace all sprinkler or test a sample of sprinklers to verify response characteristics *		
20 Years and every 10 years thereafter	Fast response sprinklers and extra high temperature sprinklers		Replace all sprinkler or test a sample of sprinklers to verify response characteristics*		
50 Years and every 10 years thereafter	Standard sprinklers		Replace all sprinkler or test sample closed-head sprinklers to verify response characteristics *		

Frequency	Component	Sub-component (if applicable)	Task	Record of Completion	Date
Following system modification or repair	Main drain (following maintenance or repair action requiring the water supply to be shut off)		Conduct main drain test to verify supply (valve position)		
			Compare results with result from previous main drain tests and original acceptance test		
			Verify that the results are within acceptable limits or identify corrective measures		
			Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge		

\* A representative sample of sprinklers for testing must consist of one (1) percent of the sprinklers installed of the same type, with a minimum of four (4) sprinklers sampled. Submit sprinklers to a recognized testing laboratory (NRTL) for these tests.

## C. Nitrogen Generation System

These ITM items should be part of the preaction systems ITM (however these requirements are new to the October 2021 edition of UFC 3-601-02 and are shown shaded).

Frequency	Component	Sub-component (if applicable)	Task	Record of Completion	Date
Monthly	Generation System		Verify generation system is free of physical damage.		
			Verify proper valve positions		
			Verify generation system is in normal operating condition.		
			Verify the power wiring to the generation system is free of physical damage.		
			Verify piping from generation system to system served is intact and free of physical damage.		
Annually	Filter Elements		Replace the activated carbon and coalescing filter elements.		
	Intake Filters		Clean the air compressor intake filter elements, replace intake filters if necessary.		
	Strainer Screens		Clean air tank blow-down strainer screens.		
2 Years	System Concentration		Verify the generation system is maintaining a nitrogen composition of 98% in the system served. Verify nitrogen composition at remote test locations.		
	System Operation		Verify generation system operates on the proper pressure drop and ceases operation at the proper set point.		
			Verify generation system does not overheat or present any unusual noise or vibration during operation.		

Frequency	Component	Sub-component (if applicable)	Task	Record of Completion	Date
5 Years			. Verify the means of anchoring the generation system to the structure is secure, tight, and free of physical damage.		
	Safety Relief Valves		Manually test safety relief valves.		
	Leakage Test		Inspect system served by generation system for leaks by conducting a pressure loss test.	The system is not old enough to have required this testing.	
	System Performance		Verify generation system restores normal gas pressure and concentration in the system served within the required timeframe.		

## D. Wet Pipe Sprinkler System

## Wet Pipe Maintenance Summary - Upper Tunnel WS #1

Frequency	Component	Task	Record of Completion	Date
Annually	Control valves (sealed, locked, or electrically supervised)	Verify proper valve position	Yes	04/26/2019RHT Upper Tunnel 06/25/2021RHT Upper Tunnel
	Waterflow alarm devices	Verify initiation and receipt of alarm (alternate use of alarm test line and inspectors test connection annually)	Yes	04/26/2019RHT Upper Tunnel 06/25/2021RHT Upper Tunnel
		Verify operation of exterior water flow alarm (if present)	N/A	N/A
		Verify alarm test valve alignment and tamper switch (if sealed or electrically supervised)	Yes	04/26/2019RHT Upper Tunnel 06/25/2021RHT Upper Tunnel
	Alarm valve and trim	Visually check the exterior of valves, gauges, trim alignment	Yes	04/26/2019RHT Upper Tunnel 06/25/2021RHT Upper Tunnel
		Verify valve pressure and legibility of the hydraulic nameplate	Yes	04/26/2019RHT Upper Tunnel 06/25/2021RHT Upper Tunnel
	Main drain	Conduct a main drain test to verify supply (valve position)	Yes	04/26/2019RHT Upper Tunnel 06/25/2021RHT Upper Tunnel
		Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge	Yes	04/26/2019RHT Upper Tunnel 06/25/2021RHT Upper Tunnel
		Compare results with results from previous main drain tests and original acceptance test	No	-
		Verify that the results are within acceptable limits or identify corrective measures	No	-
	Fire department connection	Verify accessibility and condition	Yes	04/26/2019RHT Upper Tunnel 06/25/2021RHT Upper Tunnel
		If caps are removed or missing, check for obstructions	Yes	04/26/2019RHT Upper Tunnel 06/25/2021RHT Upper Tunnel

Frequency	Component	Task	Record of Completion	Date
		Verify system check valve is not leaking	Yes	04/26/2019RHT Upper Tunnel 06/25/2021RHT Upper Tunnel
		Verify gaskets are present	Yes	04/26/2019RHT Upper Tunnel 06/25/2021RHT Upper Tunnel
		Lubricate if swivels do not rotate smoothly	Yes	04/26/2019RHT Upper Tunnel 06/25/2021RHT Upper Tunnel
		Verify proper operation of ball drip drain prior to the cold season	N/A	N/A
2 Years	Control Valves	Operate valve through entire travel to verify function	Yes	04/26/2019RHT Upper Tunnel 06/25/2021RHT Upper Tunnel
		Lubricate valves and stems to ensure operability	Yes	04/26/2019RHT Upper Tunnel 06/25/2021RHT Upper Tunnel
		Verify that valve supervisory switches detect a change in valve position	Yes	04/26/2019RHT Upper Tunnel 06/25/2021RHT Upper Tunnel
5 Years	Alarm Valve	Clean and inspect the interior to verify condition	The facility is not old enough nor have system modifications or repairs been made to have required this testing.	
	Strainers	Inspect internally and clean to good condition		
	Automatic Air Release	Confirm proper operation		
	Gauges	Calibrate or replace gauges		
10 Years				
20 Years	Fast response sprinklers and extra high temperature sprinklers	Replace all sprinklers		
50 Years and every 20 years thereafter	Standard sprinklers	Replace all sprinkler or test sample closed-head sprinklers to verify response characteristics *		
Following system modification or repair	Main drain (following maintenance or repair action	Conduct main drain test to verify supply (valve position)		
		Compare results with result from previous main drain tests and original acceptance test		

Frequency	Component	Task	Record of Completion	Date
	requiring the water supply to be shut off)	Verify that the results are within acceptable limits or identify corrective measures		
		Document static and residual pressure readings on a 3-inch by 5-inch tag and secure it to the system pressure gauge		

\* A representative sample of sprinklers for testing must consist of one (1) percent of the sprinklers installed of the same type, with a minimum of four (4) sprinklers sampled. Submit sprinklers to a recognized testing laboratory (NRTL) for these tests.

## Wet Pipe Maintenance Summary - Upper Tunnel WS #2

Frequency	Component	Task	Record of Completion	Date
Annually	Control valves (sealed, locked, or electrically supervised)	Verify proper valve position	Yes	04/26/2019 RHT Upper Tunnel 06/25/2021 RHT Upper Tunnel
	Waterflow alarm devices	Verify initiation and receipt of alarm (alternate use of alarm test line and inspectors test connection annually)	Yes	04/26/2019 RHT Upper Tunnel 06/25/2021 RHT Upper Tunnel
		Verify operation of exterior water flow alarm (if present)	N/A	N/A
		Verify alarm test valve alignment and tamper switch (if sealed or electrically supervised)	Yes	04/26/2019 RHT Upper Tunnel 06/25/2021 RHT Upper Tunnel
	Alarm valve and trim	Visually check the exterior of valves, gauges, trim alignment	Yes	04/26/2019 RHT Upper Tunnel 06/25/2021 RHT Upper Tunnel

## E. Site Water Supply

Frequency	Component	Task	Record of Completion	Date
Annually	Control valves (sealed, locked, or electrically supervised)	Verify proper valve position		
	Water Level (with remote electric supervision of water level)	Verify proper water level in tank.		
	Tank	Inspect exterior for condition, damage, corrosion, and accessibility		
	Cathodic Protection	Inspect to ensure proper operation		
2 Years	Control Valves	Operate valve through entire travel to verify function		
		Lubricate valves and stems to ensure operability		
		Verify that valve supervisory switches detect a change in valve position		
		Test water level alarms to verify operability and set points.		
3 Years	Automatic Fill Valve	Actuate valve automatically by lowering the water level in the tank		
		Measure refill rate and record data.		
	Tank Vent	Inspect and clean tank vents.		
	Tank (without cathodic protection)	Conduct internal tank inspection to determine condition and amount of corrosion.		
5 Years	Tanks (with cathodic protection)	Conduct internal tank inspection to determine condition and amount of corrosion.	The facility is not old enough nor have system modifications or repairs been made to have required this testing.	
	Pressure Gauges	Calibrate or replace gauges		
	Check Valves	Inspect interior of valves.		
	Level Indicator Test	Calibrate level indicator		

Frequency	Component	Task	Record of Completion	Date
	Automatic Fill Valve	Perform internal inspection of automatic fill valve.		

**F. Fire Department Connections**

Hose outlets and FDCs inspection, test and maintenance is conducted with the wet pipe sprinkler system. See Section C – Wet Pipe Sprinklers for more information

## G. Fire Pump System

## Fire Pump 1

Frequency	Component	Task	Record of Completion	Date	Issues
Monthly	Pump House	Inspect for proper condition, ventilation, and heating	Yes	08/20/2019	05/06/2020 Pump started smoking
	Pressure Gauges	Check reading and verify gauge operability	Yes	10/29/2019	06/02/2020 Churn not performed
				11/21/2019	10/21/2020 Churn not performed
	Controllers	Inspect electric connections	Yes	12/04/2019	11/10/2020 Churn not performed
		Operate manual and automatic starting methods	Yes	01/09/2020	12/07/2020 Churn not performed
		Verify that automatic controllers are in the automatic (AUTO) setting	Yes	02/07/2020	01/05/2021 Churn not performed
				03/20/2020	02/09/2021 Churn not performed
				04/20/2020	03/31/2021
				05/06/2020	Relief valves not operated
	Pumps			06/02/2020	Churn not performed
		Start and churn to verify operability. (Where equipment permits, allow water to flow back to the source.) [Operate electric pumps for 10 minutes.]	Yes	08/10/2020	05/18/2021 Churn not performed
				09/11/2020	06/22/2021 Churn not performed
				10/21/2020	07/02/2021
				11/10/2020	Melted packing clogging drain
				12/07/2020	Reducer is showing heavy signs of corrosion
		Verify operation of relief valves	Yes	01/05/2021	Noticeable vibrations and shavings after running.
				02/09/2021	Brushing needs replacement
				03/31/2021	Churn not performed
				05/18/2021	08/05/2021 Churn not performed
				06/22/2021	01/10/2022
				07/02/2021	Vibrations coming from pump on startup, unable to run for 10 minutes
				08/05/2021	
				09/08/2021	
				11/03/2021	
				12/01/2021

				RHT Fire Pump 1	

Frequency	Component	Task	Record of Completion	Date	Issues
	Pump House	Check packing leakage for proper water lubrication			
		Verify proper drainage			
	Controllers	Resolve all trouble indications			
		Verify proper valve position	Yes	08/20/2019 10/29/2019 11/21/2019 12/04/2019 01/09/2020 02/07/2020 03/20/2020 04/20/2020 05/06/2020 06/02/2020 08/10/2020 09/11/2020 10/21/2020 11/10/2020 12/07/2020 01/05/2021 02/09/2021 03/31/2021 05/18/2021 06/22/2021 07/02/2021 08/05/2021 09/08/2021 11/03/2021 12/01/2021 01/10/2022	
	Control valves				

Frequency	Component	Task	Record of Completion	Date	Issues
				RHT Fire Pump 1	
Annually	Control Valves	Operate valve through entire travel to verify function	Yes	06/22/2021	
2 Years	Control Valves Pumps	Lubricate valves and stems to ensure operability Verify that valve supervisory switches detect a change in valve position Check coupling alignment to ensure that the shaft is aligned	Yes	06/22/2021	
	Pumps	Check pump shaft end play			06/22/2021 Not performed
	Relief valves	Lubricate bearings	Yes	06/22/2021	06/22/2021 Not performed
	Emergency power supply	Calibrate valves Test to verify availability and capacity for pump motor	Yes	06/22/2021	06/22/2021 Not performed
5 Years	Pump	Conduct flow test to verify pump output. Test may be through a flow meter returning the water to a storage reservoir or through the test header. Recirculation of water to the suction piping is not permitted. In a multi-pump installation, each pump may be tested separately at not less than 100 percent design capacity for 30 minutes.			Facility is not old enough to have required this testing.

## Fire Pump 2

Frequency	Component	Task	Record of Completion	Date	Issues
Monthly	Pump House	Inspect for proper condition, ventilation, and heating	Yes	08/20/2019	01/09/2020 Pump smoking from bearings, further investigation needed, pump should not be run anymore, until issue is resolved.
	Pressure Gauges	Check reading and verify gauge operability	Yes	11/21/2019 12/04/2019	
	Controllers	Inspect electric connections	Yes	01/09/2020	02/07/2020 Churn not performed, Did not operate pump due to smoking issue, possible air leak in suction line or pump packing failure.
		Operate manual and automatic starting methods	Yes	02/07/2020 04/20/2020	
		Verify that automatic controllers are in the automatic (AUTO) setting	Yes	05/06/2020 07/02/2020	04/20/2020 Pump still smoking, after troubleshooting identified packing is overheating and not allowing water to cool the pump shaft. Recommend packing replacement.
		Start and churn to verify operability. (Where equipment permits, allow water to flow back to the source.) [Operate electric pumps for 10 minutes.]	Yes	08/10/2020 09/11/2020	
	Pumps	Verify operation of relief valves	Yes	10/21/2020 11/10/2020 12/07/2020 01/05/2021 02/09/2021 03/31/2021 05/18/2021 07/02/2021 08/05/2021 09/08/2021 11/03/2021 12/01/2021 01/10/2022	05/06/2020 Pump still smoking, after troubleshooting identified packing is overheating and not allowing water to cool the pump shaft. Recommend packing replacement. 07/02/2020 28. Upon arrival placed system on test, & isolated Fire Pump #2. After previously reassembling packing & recharging system we turned Fire pump on & ran for the full 10 mins. Both Pumps need to be opened up, cleaned, & repacked so we can adjust packing to proper drip rate, & make adjustments as we run pump. After repacking recommend running weekly. Deficiencies: 1. Fire Pump needs to be cracked open cleaned & repacked to prevent further clogging drainage. 2. 1/2" x 1/4" reducer for Fire Pump #2 sensing line gauge above FP by 8" check valve has pin hole leak needs to be replaced. 3. 2 Bolts for 8" check valve on Fire Pump #2 (Tyco CV-1) have rusted & need to be replaced 09/11/2020 Churn not performed 10/21/2020 Churn not performed 11/10/2020 Churn not performed

					08/05/2021 Slight AFFF leak found below pump, recommend replacing seal for one rated for corrosive liquids. Left out of service
					09/08/2021 Slight AFFF leak found below pump, recommend replacing seal for corrosive Liquids. Pump off due to underground leak
					11/03/2021 Slight leak under pump recommend replacing seal. Pump off due to underground leak

Frequency	Component	Task	Record of Completion	Date	Issues
2 Years	Control Valves	Operate valve through entire travel to verify function	Yes	06/22/2021	12/01/2021 Slight leak under pump recommend replacing seal. Pump off due to underground leak
		Lubricate valves and stems to ensure operability			01/10/2022 Slight leak under pump recommend replacing seal. Pump off due to underground leak
		Verify that valve supervisory switches detect a change in valve position			06/22/2021 Not performed
	Pumps	Check coupling alignment to ensure that the shaft is aligned			06/22/2021 Not performed
		Check pump shaft end play			06/22/2021 Not performed
5 Years	Relief valves	Lubricate bearings	Yes	06/22/2021	06/22/2021 Not performed
		Calibrate valves			06/22/2021 Not performed
	Emergency power supply	Test to verify availability and capacity for pump motor			06/22/2021 Not performed
	Pump	Conduct flow test to verify pump output. Test may be through a flow meter returning the water to a storage reservoir or through the test header. Recirculation of water to the suction piping is not permitted. In a multi-pump installation, each pump may be tested separately at not less than 100 percent design capacity for 30 minutes.			Facility is not old enough to have required this testing.

## H. Fire Alarm and Mass Notification System

Mass Notification ITM items should be part of this summary (however these requirements are new to the October 2021 edition of UFC 3-601-02 and are shown shaded).

FLC Adit 1 Fire Alarm MNS Maintenance Summary

Frequency	Component	Sub-component (if applicable)	Task	Record of Completion	Date	
Annually	Control Panel and Annunciator Equipment (monitored)		Test to verify proper receipt of alarm, supervisory, and trouble signals (inputs, one of each type) and operation of notification appliances and auxiliary functions (outputs, one of each type).	Yes	12/20/2019 (FLC	(b) (3) (A) Node 1 FA 19120), and Node 6 19120), Node 6 20122), Node 6 FA - Nov 15, 2021), Node 2), Node 1 FA),

**I. AFFF Retention System**

There are no UFC 3-601-02 Fire Protection System Inspection, Testing and Maintenance requirements for the retention system.

**J. Maintenance Records Summary of Findings**

The review of the maintenance records highlighted the following issues:

1. For most systems annual inspections are not being performed annually, typically these inspections are happening on a 2-year cycle.
2. Items identified in an annual report as requiring repair were often re-identified in a follow-on annual report (typically performed ~2 years later)– meaning that repairs were not made for more than 2-years.
3. The Kingfisher Radio transmitter was identified on 11 annual test reports as not transmitting to the Regional Dispatch Center. These incidents occurred on tests occurring over the period 10/19/2019 through 02/16/2022 – with 2 incidents in late 2019, 5 incidents in 2020, 2 incidents in 2021 and 2 incidents in early 2022. During this same period there were 11 fire alarm tests on other days in which signals were reported as being received at the RDC – 2 tests in late 2019, 5 tests during 2020, and 4 tests in 2021. Based on these results there appears to be only a 50% success rate in transmitting signals to the RDC.
4. The testing documentation and tests being performed are based on NFPA 72 requirements, rather than on the requirements of UFC 3-601-02.
5. To date no testing of Mass Notification specific panels has been incorporated into the testing program. This is a new requirement of the October 2021 edition of UFC 3-601-02.

## PART 2 – SUMMARY OF FINDINGS

### 1. FIRE PROTECTION SYSTEMS

Findings/recommendations for fire protection system repairs are as follows:

1. The hose valves are provided with pressure-regulating devices but were not provided with a valved outlet for a pressure gauge to be connected. A valved outlet should be provided for each location with a pressure-regulating device so a pressure gauge can be attached to verify the required pressure is being provided.
2. Significant external pipe degradation was observed in the riser for Preaction System 3 due to the constant dripping of ground water seepage into the riser closet and onto the piping. A ceiling should be constructed in this room, like the metal ceiling constructed in other areas of the Lower Tunnel, to stop water dripping in this room and the degraded riser piping should be replaced.
3. The fire department connections were not provided with signs indicating the system they served, and the operating pressures required. An appropriate sign should be provided at each fire department connection.
4. A significant number of fire alarm visual notification devices were over-spaced creating code deficient conditions. These devices are spaced beyond the maximum distance allowed by NFPA 72 of 100 feet. This occurs at several intervals, where a device will be spaced 110 – 120 feet from the previous device, and then 70 – 80 feet to the next device. There did not appear to be any field conditions which would contribute to the extended spacing. Spacing of these devices should be corrected so they are within the code required spacing.
5. There are also numerous fire alarm system device label errors, mostly of single, isolated devices, that should be corrected.
6. All the explosion-proof fire alarm strobes located in the Tank Farm portion of the Lower Tunnel are obstructed and violate NFPA 72. The code requires strobes to be visible by direct concentrated viewing (i.e., you must be able to see the actual strobe lens from all parts of the corridor) to use corridor spacing of minimum 15cd strobes mounted up to 100 feet apart. The strobes in this section of the tunnel are mounted with the bottom of the strobe lens well above the adjacent pipe stand structure and pipes. Personnel on the actual walking portion of the tunnel do not have a direct line of sight to the strobes. The location of these devices should be corrected to allow viewing by tunnel users.
7. The fire alarm Kingfisher Radio transmitter appears to be non-functional an inordinate amount of the time. Further investigation is required to determine why the Kingfisher transmitter is not

continuously communicating with the Regional dispatch center. Design improvements/repairs are required to ensure continuity of fire alarm signal transmission.

8. The sequence of operations of the fire protection and AFFF retention system is complex and there is no operations manual that clearly illustrates the interrelation between these two systems. An operations manual should be developed so that tunnel operators understand the operation of the systems. To ensure the correct sequence of operations of these systems the fire protection and AFFF retention systems should be recommissioned to confirm these systems are operating per the requirements of the final sequence of operations.

If the facility were to be maintained in operational condition for continued fuel operations, then the following additional items would be recommended:

1. In numerous specific instances the as-built drawings do not accurately represent the installed conditions. The as-built drawings across all disciplines should be updated to match actual installed conditions.
2. There were also inaccuracies associated with equipment shown on the as built drawings not being installed, or installed in a different orientation (i.e., mounting on wall instead of ceiling, or vice-versa). Many of these examples involved duct-mounted smoke detection at smoke dampers, usually where installation of this type of device was not possible. However, there was no documentation indicating the required detection was exempted nor was spot detection provided at the damper. Some of this may be attributable to the fact the drawings provided and reviewed would not necessarily reflect changes associated with Revisions R and S (dated 21 June 2018) of the design drawings, some of which affected systems monitored by the fire alarm and mass notification system. The as-built drawings be updated to match installed conditions.

## 2. RETENTION SYSTEM

There are numerous improvements that could be recommended to the operation of the retention system. However, at this stage with the established goal of ultimately taking the fuel storage tanks out of service within the next 2-3 years any recommendations for significant alterations to the retention system do not appear to be warranted. Confirmation of the correct sequence of operation of the system, as recommended in item 8 above, should be performed.

## 3. FIRE PROTECTION SYSTEM MAINTENANCE

1. A complete overhaul of the fire protection system maintenance program to align it with UFC 3-601-02 requirements and better oversight to confirm timely ITM is being provided could be recommended. However, at this stage with the established goal of ultimately taking the fuel storage tanks out of service within the next 2-3 years any recommendations for significant alterations to the fire protection ITM program does not appear warranted.

## PART 3 – RECOMMENDED BETTERMENTS

If the facility was to remain as an operational fuel storage facility our recommendations for betterments are as follows:

1. Upgrades the AFFF retention system to permit the collection of effluent in the area outside (b) (3) (A) under gravity flow should be made.
3. Establish a standalone ITM program for Red Hill. Due to the critical nature of this facility this program should be funded and directly overseen by the Red Hill Facility managers independent of any other ITM programs on the base.

The Scope of work listed achieving faster response by fire detection/protection systems as a potential betterment. However, this would not appear to be warranted. The flame detection system installed is reasonable quick with an adequate false activation rejection rate. There appears to be no significant benefit, or obvious candidate, for a faster detection and fire protection activation.

## **APPENDIX B. SITE SURVEY NOTES PREACTION FOAM/WATER SPRINKLER SYSTEM**

ALL TYPE 2 N2-BLAST MUST BE WALL MOUNTED. WALL MOUNTING BRACKETS ARE INCLUDED WITH UNIT

1/4" MNPT FILTER DRAIN CONNECTION

FILTERS ARE TO BE CHANGED ANNUALLY

1" AIR / NITROGEN SUPPLY TO FPS PIPING

5HP AIR COMP. WITH MIN 80 GAL REC. TANK

1/4" NPT TANK DRAIN

REFRIGERATED AIR DRYER

3/8" OD DRAIN LINE

28 GALLON NITROGEN STORAGE TANK PROVIDED WITH WALL BRACKETS AND STRAP

110V / 60Hz / 1PHASE NITROGEN GENERATOR HAS A 1/2" CONDUIT KNOCKOUT UNDERNEATH CABINET'S PANEL FOR POWER SUPPLY TO ELECTRICAL PANEL. REFER TO DRAWING ES-TYPEN FOR PROPER CONNECTIONS

PRE-ACTION SYSTEM CAPACITIES:

- ZONE 1: 614 GALLONS
- ZONE 2: 573 GALLONS
- ZONE 3: 629 GALLONS
- ZONE 4: 646 GALLONS
- ZONE 5: 649 GALLONS
- 1" SUPPLY LINE: 112.5 GALLONS
- TOTAL CAPACITY: 3,223.5 GALLONS

MODEL PROVIDED: FPS-6000 (6,000 GALLON CAPACITY)

## **APPENDIX C. SITE SURVEY NOTES FIRE PUMP SYSTEM**

FIRE PUMP ROOM - EQUIPMENT LEGEND

- 1. 10" VERTICAL 77H GRV GSKY VALVE W/TAMPER (250PSI)
- 2. 12" T100 BFM-W WATER BUTTERFLY VALVE WITH TAMPER (250PSI)
- 3. 12" T100 CV-IF GRV CHECK VALVE (300PSI)
- 4. FIRE PUMP CONTROLLER W/TAMPER SWITCH
- 5. ELECTRIC FIRE PUMP - 2,500 GPM @ 70 PSI
- 6. 1" AUX DRAIN
- 7. 10" NBDO GD-6785-8N BUTTERFLY VALVE WITH TAMPER SWITCH
- 8. 8" NBDO GD-4762-8N BUTTERFLY VALVE WITH TAMPER SWITCH
- 9. 8" FLOW METER
- 10. JOCKEY PUMP CONTROLLER
- 11. 25 GPM @ 125 PSI JOCKEY PUMP
- 12. 1/4" MILWAUKEE BB-SC100 BUTTERBALL VALVE (NO TAMPER STANDARD 175 PSI)
- 13. NOT USED
- 14. 1/4" MILWAUKEE BB-SC100 BUTTERBALL VALVE (NO TAMPER - SPEC. ORDER 350 PSI NVC)
- 15. 1/4" FPM THREADED CHECK VALVE (CU)
- 16. SPT-14 - 106 GAL FIRE PUMP SURGE TANK - SIZED PER MANU. FORMULA
- 17. 4" GROOVED B-FLY VALVE WITH TAMPER - NBDO GD-4785-8N 300PSI
- 18. 1/4" 175 PSI PRESSURE RELIEF VALVE (PPE TO DRAIN)
- 19. 300 PSI WATER PRESSURE GAUGE
- 20. AUTOMATIC AIR RELEASE VALVE
- 21. 4" WING M-2 GRV CHECK VALVE (250 PSI)
- 22. CRACKER 6410-P8 POLISHED BRASS DOUBLE CLAPPER 2-WAY FIRE DEPARTMENT CONNECTION W/ ROUND PLATE "AUTO SPRK" & FLUJIS
- 23. 3" KENNEDY KS-FM FLG NON RISING STEM GATE VALVE (200 PSI) WITH WALL POST INDICATOR AND SUPERVISORY SWITCH
- 24. 3" WING L-1 FLG-GRV ALARM VALVE WITH VERT VARIABLE PRESSURE TRIM + RETARD + PRESSURE SWITCH (300 PSI)
- 25. WATER MOTOR & ALARM GONG ON OUTSIDE OF BUILDING
- 26. 10" NBDO GD-6785-8N BUTTERFLY VALVE WITH TAMPER SWITCH (300PSI)
- 27. 10" T100 CV-IF GRV CHECK VALVE (300PSI)
- 28. AUTOMATIC AIR RELEASE
- 29. 3" CASING RELIEF SET TO 240 PSI - PPE TO FLOOR DRAIN
- 30. 300 PSI OIL FILLED WATER PRESSURE GAUGE
- 31. AIR COMPRESSOR
- 32. AIR DRYER
- 33. NITROGEN GENERATOR
- 34. NITROGEN TANK
- 35. AIR MAINTENANCE DEVICE

NOTE: PROVIDE SIGNAGE ON VALVES INDICATING NORMAL OPERATING POSITION (OPEN OR CLOSED) - CHAIN & LOCK ALL

- 4" GROOVED B-FY VALVE WITH TAMPER - NIBCO QD-4765-BN 300PSI
- 1/4" 175 PSI PRESSURE RELIEF VALVE (PPE TO DRAIN)
- 300 PSI WATER PRESSURE GAUGE
- 4" AUTOMATIC AIR RELEASE VALVE
21. CROCKER 6410-PB POLISHED BRASS DOUBLE CLAPPER 2-WAY FIRE DEPARTMENT CONNECTION
- W/ ROUND PLATE "AUTO STOP" & PLUGS
- 3" KONGERD KS-FH FUG NON RISING STEM GATE VALVE (200 PSI) WITH WALL POST INDICATOR AND SUPERVISORY SWITCH
- 3" VIKING J-1 FUG-GRV ALARM VALVE WITH VERT. VARIABLE PRESSURE TRIM + RETARD + PRESSURE SWITCH (300 PSI)
25. WATER MOTOR & ALARM GONG ON OUTSIDE OF BUILDING
- 10" NIBCO QD-4765-BN BUTTERFLY VALVE WITH TAMPER SWITCH (300PSI)
- 10" TYP C4-IF GRV CHECK VALVE (300PSI)
- AUTOMATIC AIR RELEASE
- 3" CASING RELIEF SET TO 240 PSI - PPE TO FLOOR DRAIN
- 300 PSI OIL FILLED WATER PRESSURE GAUGE
- AIR COMPRESSOR
- AIR DRYER
33. NITROGEN GENERATOR
34. NITROGEN TANK
35. AIR MAINTENANCE DEVICE

NOTE: PROVIDE SIGNAGE ON VALVES INDICATING NORMAL OPERATING POSITION. (OPEN OR CLOSED) - CHAIN & LOCK ALL SEE SHEET FB-503 FOR PUMP SCHEDULES

FIRE PUMP - SECTION FACING EAST (B-B)

FIRE PUMP ROOM - SECTION FACING SOUTH (A-A)

IF SHEET IS LESS THAN 24" X 36" REDUCED PRINT - USE GRAPHIC SCALES

THE CONTRACTOR SHALL BE RESPONSIBLE FOR OBTAINING THE WORK AND MATERIALS NEEDED TO COMPLETE THE WORK AND TO INSURE THE INSTALLATION OF ALL WORK WITHIN THE AVAILABLE SPACE.

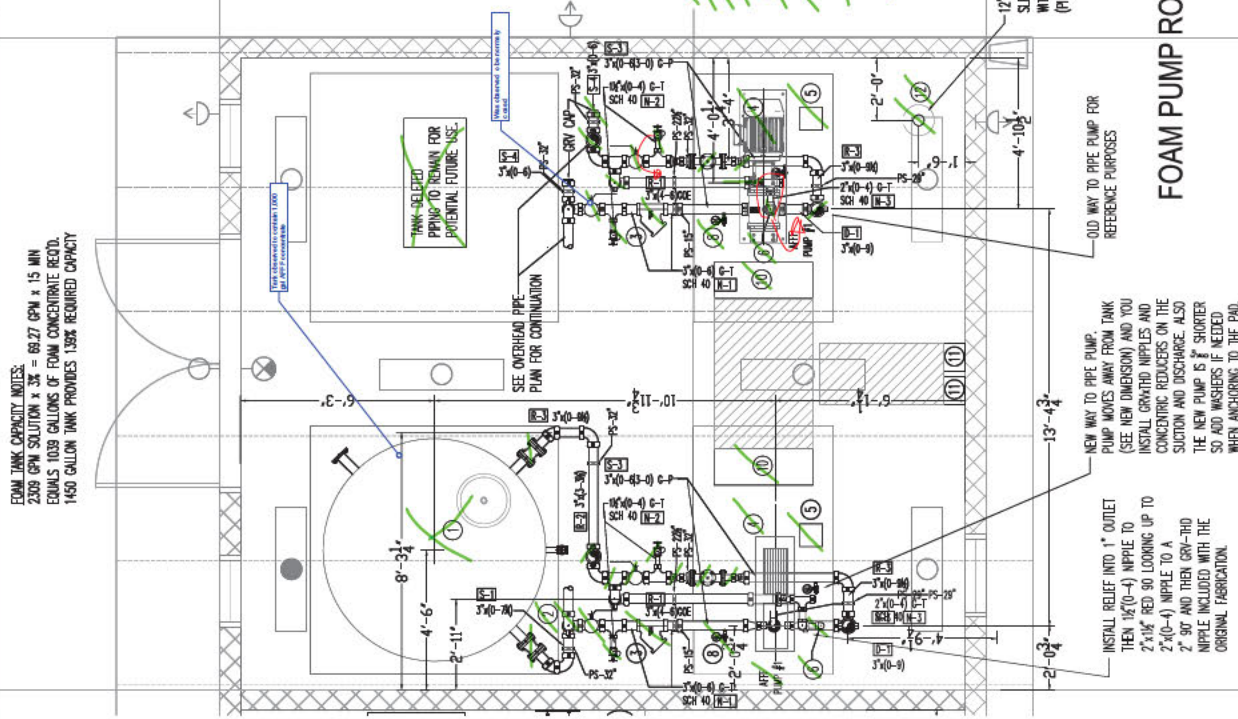

## **APPENDIX D. SITE SURVEY NOTES FOAM PUMP SYSTEM**

# FOAM TANK CAPACITY NOTES:

2300 GPM SOLUTION x 3% = 69.27 GPM x 15 MIN  
EQUALS 1039 GALLONS OF FOAM CONCENTRATE REQ'D.  
1450 GALLON TANK PROVIDES 138% REQUIRED CAPACITY

## FOAM PUMP ROOM - LOW PIPING

## FOAM PUMP ROOM - EQUIPMENT LEGEND

- 1450 GALLON FOAM CONCENTRATE TANK
- STAINLESS STEEL BALL VALVE WITH TAMPER SWITCH
- STRAINER
- 146 GPM @ 150 PSI FOAM PUMP
- JOCKEY PUMP 3 GPM @ 160
- PRESSURE RELIEF VALVE
- COMPOUND PRESSURE GAUGE
- PRESSURE GAUGE
- FOAM PUMP CONTROLLER W/A.T.S.
- FOAM JOCKEY PUMP CONTROLLER
- DISCHARGE TO UNDERGROUND
- NOT USED
- CHECK VALVE - 3" NBCCO T-433-B

NOTE: PUMP SHD TO BE FILLED WITH CONCRETE PER MANUFACTURER'S RECOMMENDATIONS.

12" DIAMETER FLOOR SLEEVE FOR 4" FOAM LINE WITH 8" CONTAINMENT (PIPED BY OTHERS)

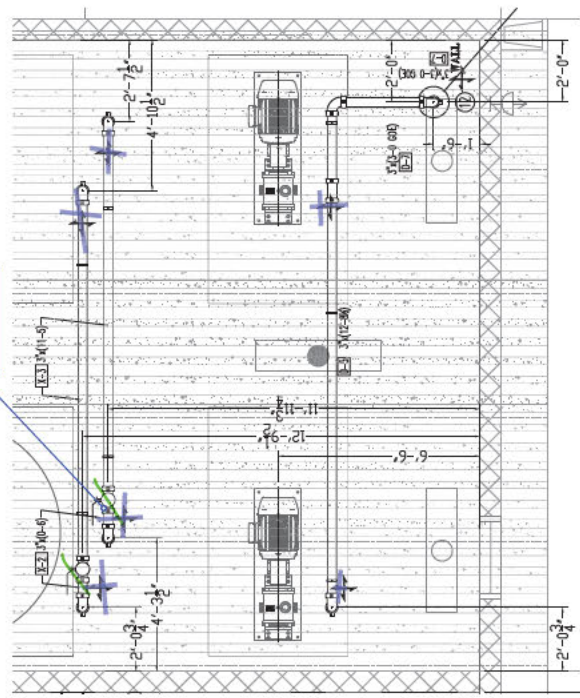

OLD WAY TO PIPE PUMP FOR REFERENCE PURPOSES

INSTALL RELIEF INTO 1" OUTLET THEN 1/2" (10'-0") NIPPLE TO 2'-1/2" RED 90 LOOKING UP TO 2'-0" (10'-0") NIPPLE TO A 2' 90" AND THEN GRW-THD NIPPLE INCLUDED WITH THE ORIGINAL FABRICATION.

THE CONTRACTOR SHALL BE RESPONSIBLE FOR OBTAINING THE NECESSARY PERMITS AND INSURING THE WORK. THE CONTRACTOR SHALL BE RESPONSIBLE FOR THE INSTALLATION OF ALL WORK WITHIN THE AVAILABLE SPACE.

IF SHEET IS LESS THAN 24" x 36" REPERED PRINT - USE GRAPHIC SCALES

**STATUS AS OF SURVEYING - FRIDAY MARCH 25 2022.**

Remaining areas -

1. Upper Tunnel from (b)(3)(A) intersection to Tanks 19/20 End
2. UGPH - Both Upper and Lower Levels
3. Harbor Tunnel (b)(3)(A)
4. Fire Pump House
5. Fire Water Tanks
6. AFFE effluence Retention Tank

**REPEATS**

- Lower Tunnel Elec Rooms at (b)(3)(A)
- Upper Tunnel top of Tank 1 (NEED FALL PROTECTION)

**PARTIAL SITE ISOMETRIC**

SCALE: 1" = 10'

ALL EXPLIGHTS WERE  
 OUT EXCEPT AT TOP OF  
 TANK-EXTREMELY D.M.

EMR is splrd, why no shunt  
 trip? Check Gauger Office.

No detectors or any evidence of  
 FSDs, despite penetrating elev lobby,  
 elev shaft, and next tank door.

32 feet  
 from wall

35 feet from wall

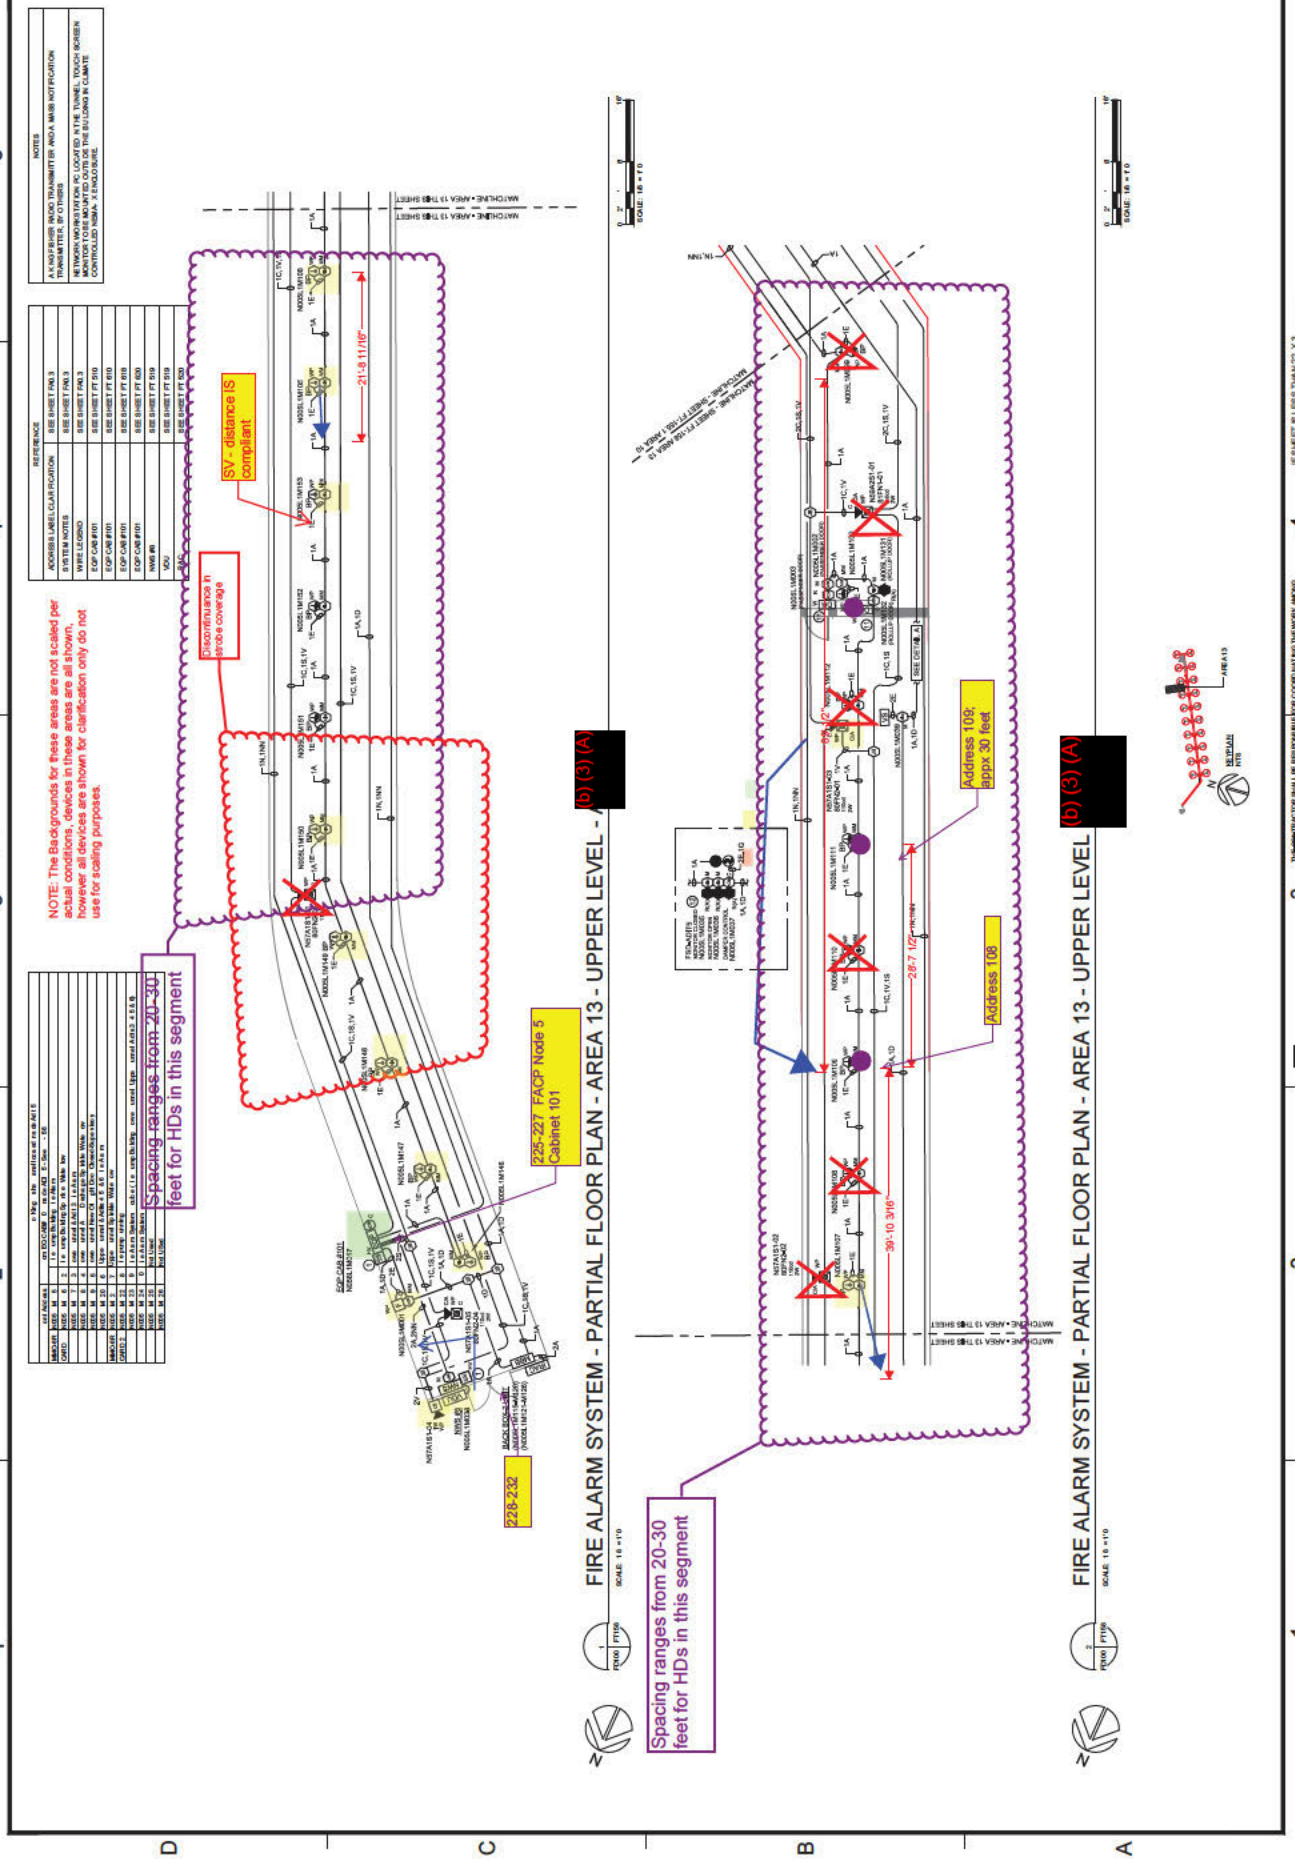

249 DO with exposed wiring  
 (no jacket, individual  
 conductors); installed in an  
 elbow; manual inside housing;  
 UL violation

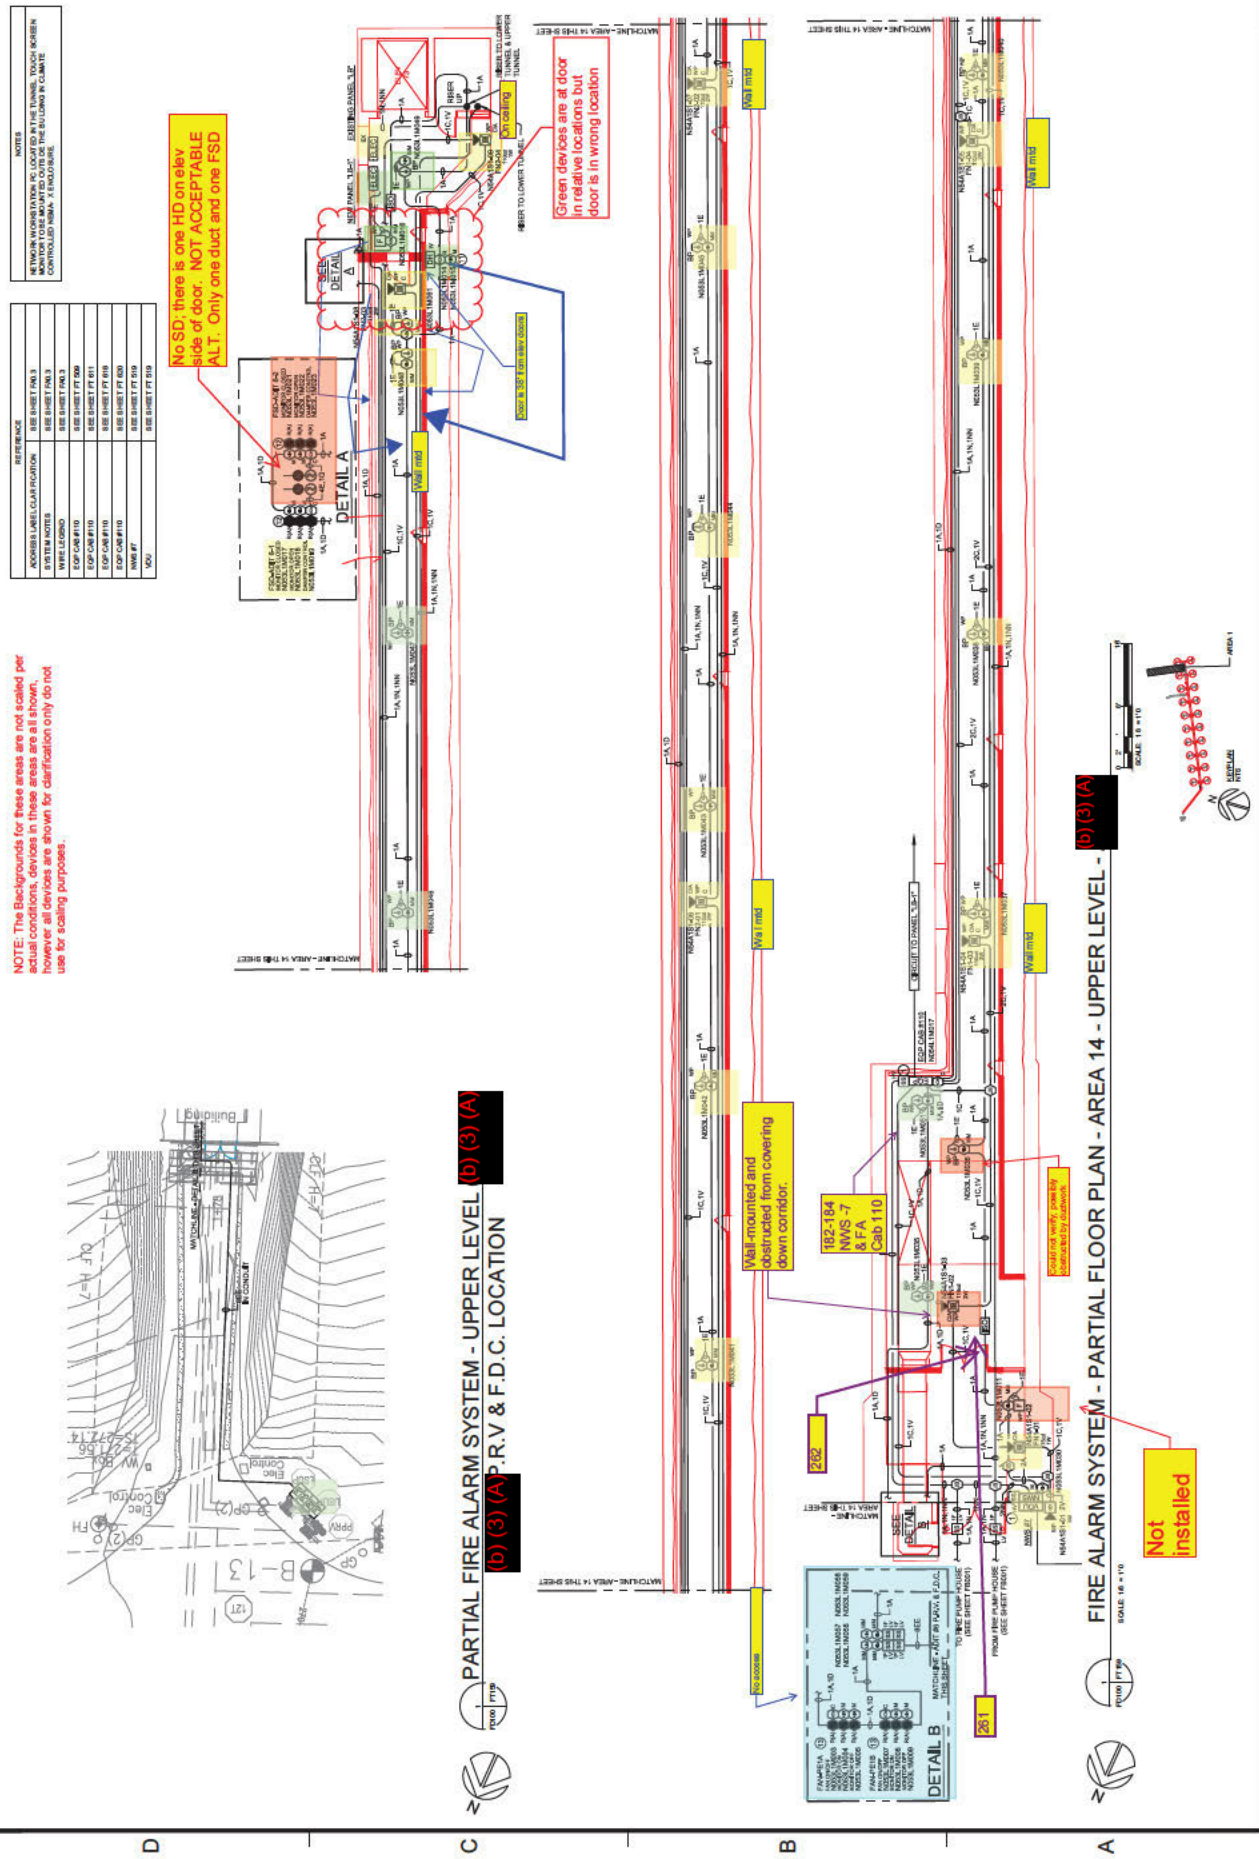

246 Completely  
 inaccessible for  
 maintenance
